

Western Electric

301A

301A Vacuum Tube

Classification—Full wave, thermionic, mercury vapor rectifier

The 301A vacuum tube is designed to supply direct current from an alternating-current supply.

Dimensions—The dimensions and outline diagrams are given in Figures 1 and 2. The overall dimensions are:

| | |
|-----------------------|------|
| Maximum length..... | .6½" |
| Maximum diameter..... | .2½" |

Mounting—The 301A employs a standard 4 pin thrust type base suitable for use in a Western Electric 143B or similar socket. Base dimensions and the arrangement of electrode connections to the base terminals are shown in Figs. 1 and 2.

The tube should be mounted in a vertical position with the base end down. There should be a free circulation of air around the tube. No object should touch the glass bulb.

Filament Rating

| | |
|-------------------------------|-------------|
| Filament voltage..... | 5.0 volts |
| Nominal filament current..... | 3.0 amperes |

The filament of this tube is designed to operate on a voltage basis from an alternating-current supply. The voltage should be maintained to within 5% of its rated value (5.0 volts). Operation

FILE: RECTIFIER TUBE SECTION

American Telephone and Telegraph Company 1963

of the filament at a voltage above the upper limit will definitely reduce the life of the tube while a decrease in voltage below the lower limit may cause immediate failure.

Sufficient time must always be allowed for the filament temperature to reach its normal operating value before the anode potential is applied. If filament circuits with good regulation are used, this time is 30 seconds. If the tube is operated at ambient temperatures below 20° C., a longer period of time is required for the purpose of bringing the mercury vapor pressure to a satisfactory operating value. The minimum filament warming time as a function of ambient temperature is shown in figure 3.

For proper distribution of the mercury a period of 10 to 15 minutes filament warming time should be allowed when the tube is used for the first time or if it has been reinserted in the apparatus after having been removed.

Characteristics and Operating Conditions

| | |
|--|------------------|
| Approximate anode-cathode potential drop..... |10 volts |
| Maximum peak plate current..... |1.0 ampere |
| Maximum peak potential between electrodes..... |1800 volts |
| Maximum operating ambient temperature range..... |0 to 50° C |
| Recommended operating ambient temperature range..... |10 to 40° C |

The anode-cathode potential drop is substantially independent of the plate current. The exact value varies from tube to tube and during the life of a given tube. Within the specified ambient temperature range and plate current range, it may vary from 5 to 25 volts.

The anode-cathode drop as a function of temperature is shown on fig. 4 for a typical 301A tube after reaching temperature equilibrium and when passing the rated plate current.

The maximum permissible peak plate current (1.0 ampere) is a limitation on the instantaneous value that the tube can carry safely in the direction in which it is designed to conduct and should not be exceeded. The maximum direct load current is not fixed but will depend upon the wave form required by the load and filter circuit.

The maximum permissible peak potential between electrodes (1800 volts) is a limitation on the instantaneous value that the tube can stand safely. If it is exceeded, an arc-back may result which will injure the tube. The maximum direct potential available is not fixed but will depend upon the type of circuit used.

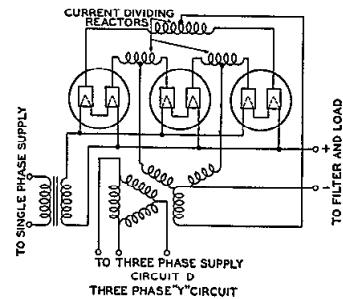

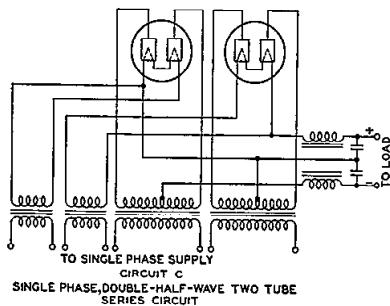

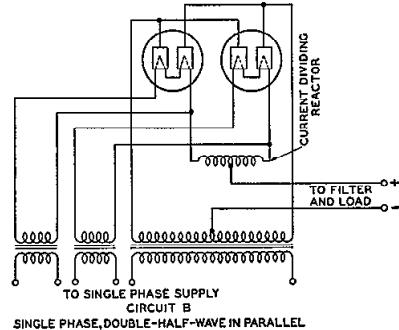

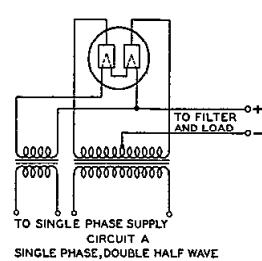

301A vacuum tubes may be operated in parallel if some provision is made to insure a proper division of the load current. Current dividing reactors or ballasting resistors in series with each anode, may be used for this purpose. The size of the reactors or resistors depends upon the circuit design.

In most cases the termination of the useful life of the 301A tube is due to the loss of filament activity. This causes the tube to fail by arcing between the electrodes. Failures of this kind should be safeguarded by proper fuse protection to prevent injury to other tubes in the circuit and to the auxiliary equipment.

Typical Rectifier Circuits—The 301A vacuum tube may be used in any standard high vacuum rectifier circuit subject to its current, voltage and temperature limitations. Typical circuits are shown below. The approximate direct output current and voltage for each type of rectifier circuit where tubes are operated at maximum permissible plate current and inverse voltage are given in Table 1. The values listed are average values of the pulsating current and voltage for an unfiltered circuit.

Table 1

| Circuit Designation | Phase Supply | Number Tubes | Load Potential in Volts | Load Current in Amperes |
|---------------------|--------------|--------------|-------------------------|-------------------------|
| A | 1 | 1 | 550 | 0.6 |
| B | 1 | 2 | 550 | 1.2 |
| C | 1 | 2 | 1100 | 0.6 |
| D | 3 | 3 | 800 | 1.6 |
| E | 3 | 3 | 700 | 1.8 |
| F | 1 | 3 | 1100 | 0.6 |

Western Electric

308B Vacuum Tube

Classification—Filamentary air-cooled triode

This tube was designed primarily for use as an audio-frequency amplifier or modulator; or as a radio-frequency oscillator or amplifier.

Dimensions—Dimensions and outline diagrams are shown in Figures 1 and 2 and are:

| | |
|-----------------------------|--------------------|
| Maximum overall length..... | 13 $\frac{5}{8}$ " |
| Maximum diameter..... | 3 $\frac{5}{8}$ " |

Copyright 1936 Western Electric Company, Incorporated

Mounting—Large four-pin bayonet base for use in a W. E. 118A or similar socket, for either vertical or horizontal mounting. If mounted horizontally the plane of the filament, which is indicated in Figure 2, should be vertical.

Filament—Thoriated tungsten.

| | |
|----------------------------------|-----------|
| Filament voltage..... | 14 volts |
| Nominal filament current..... | 6 amperes |
| Average thermionic emission..... | 4 amperes |

Approximate Direct Interelectrode Capacitances

| | |
|------------------------|---------------------|
| Plate to grid..... | 17.4 $\mu\text{f}.$ |
| Grid to filament..... | 13.6 $\mu\text{f}.$ |
| Plate to filament..... | 9.3 $\mu\text{f}.$ |

Characteristics—Performance data given below are based upon a typical set of conditions. Variations can be expected with different circuits and tubes.

Figures 3 and 4 give the static characteristics of a typical tube plotted against grid and plate voltages.

Average Characteristics at 1500 volts direct plate potential and minus 150 volts grid bias,
 $I_b = .167$ ampere.

| | |
|-------------------------------------|----------------|
| Amplification factor..... | 8 |
| Plate resistance..... | 1070 ohms |
| Grid to plate transconductance..... | 7500 micromhos |

Operation

Maximum Ratings

| | |
|--|------------------|
| Max. direct plate voltage..... | 2250 volts |
| Max. direct plate current..... | 325 milliamperes |
| Max. plate dissipation..... | 250 watts |
| Max. direct grid current..... | 75 milliamperes |
| Max. r-f grid current..... | 5 amperes |
| Max. frequency for the above ratings..... | 1.5 megacycles |
| Max. plate voltage for upper frequency limit of 4.5 Mc..... | 750 volts |
| Max. plate voltage for frequencies between 1.5 and 4.5 Mc in proportion. | |

The above are maximum ratings which do not apply simultaneously but depend on the type of service as specified below.

Class A Audio Amplifier or Modulator

| | | |
|---------------------------|-------|------------------|
| Direct plate voltage..... | 1500 | 1000 volts |
| Grid bias..... | -155 | -80 volts |
| Direct plate current..... | 135 | 210 milliamperes |
| Plate dissipation..... | 200 | 210 watts |
| Load impedance..... | 13000 | 3000 ohms |
| Undistorted output..... | 50 | 35 watts |

Class B Audio Amplifier or Modulator—for Balanced 2 Tube Circuit

| | | |
|--|------|------------------|
| Direct plate voltage..... | 1750 | 1500 volts |
| Grid bias..... | -215 | -180 volts |
| Direct plate current per tube | | |
| No drive..... | 30 | 25 milliamperes |
| Max. drive..... | 300 | 300 milliamperes |
| Plate dissipation..... | 240 | 210 watts |
| Load resistance plate-to-plate..... | 5200 | 4280 ohms |
| Load resistance per tube..... | 1300 | 1070 ohms |
| Approximate maximum output..... | 575 | 475 watts |
| Recommended power for driving stage..... | 35 | 35 watts |

Class B Radio-Frequency Amplifier

| | | |
|--|------|------------------|
| Direct plate voltage..... | 1750 | 1500 volts |
| Direct plate current..... | 215 | 250 milliamperes |
| Plate dissipation..... | 250 | 250 watts |
| Grid bias..... | -230 | -200 volts |
| Approx. carrier watts for use with 100% modulation | 125 | 125 watts |

Class C Radio-Frequency Oscillator or Power Amplifier—Unmodulated

| | | |
|---------------------------|--------------|--------------------|
| Direct plate voltage..... | 1750 | 1500 volts |
| Direct plate current..... | 300 | 300 milliamperes |
| Grid bias..... | -345 to -460 | -300 to -400 volts |
| Nominal power output..... | 350 | 300 watts |

Class C Radio-Frequency Amplifier—Plate Modulated

| | | |
|--|------|------------------|
| Direct plate voltage..... | 1250 | 1000 volts |
| Direct plate current..... | 300 | 300 milliamperes |
| Grid bias..... | -320 | -260 volts |
| Max. direct grid current..... | 75 | 75 milliamperes |
| Nominal carrier power output for use with 100% modulation..... | 250 | 200 watts |

Operating Precautions

Mechanical—Figures 1 and 2 show the overall dimensions and basing arrangement for the tube.

The tubes should not be subjected to mechanical shock or excessive vibration. Mechanical vibration may cause breakage of the thoriated tungsten filaments.

A free circulation of air must be provided to insure adequate cooling of the glass during operation.

Electrical—Overload protection should always be provided for the plate circuit. A suitable fuse or circuit breaker should remove the plate voltage if the plate current exceeds 425 milliamperes. Although the tube is sufficiently rugged to withstand momentary overloads, a prolonged overload caused by inefficient adjustment of the circuit, may damage the tube. When adjusting a new circuit, reduced plate voltage or a series resistance of 1000 to 5000 ohms in the plate circuit should be used until it is operating properly.

The filament should always be operated at the rated voltage, measured at the tube terminals. A 5% decrease in filament voltage reduces the thermionic emission approximately 25%. Either direct or alternating current may be used for heating the filament. If direct current is used, the plate and grid circuit returns should be connected to the negative filament terminal. If alternating current is used, the circuit returns should be connected to the center tap of the filament heating transformer winding or to the center tap of a resistor placed between the filament terminals. A resistance of 30 to 40 ohms of ten watt rating is suitable.

In cases where severe and prolonged overload has temporarily impaired the electronic emission of the filament, the activity may be restored by operating the filament, with the plate and grid voltages off, 30% above normal voltage for 10 minutes followed by a longer period at normal voltage.

Audio Amplifier or Modulator

Class A—Peak grid drive equal to or less than the grid bias.

Grid bias may be obtained from the drop across a resistance in the plate current return or from a battery or rectifier supply.

Plate dissipation allowable for this type of service is generally lower than is safe for other uses since the energy is dissipated in the plate in smaller areas due to relatively high voltage drop in the tube.

The plate dissipation is equal to the plate voltage multiplied by the normal plate current. Performance data are based upon the use of a resistance load. Undistorted output is calculated on the basis of 5% second harmonic distortion.

Class B—Grid bias practically at cut-off and grid driving voltage higher than the bias.

Two tubes may be used in a balanced circuit. An adequate driving stage and an input transformer with good regulation must be used so that the grid current drawn during positive grid swings does not produce appreciable distortion. The output transformer must transform the load impedance to the proper value for the tubes used. The power output obtainable will be determined by the quality of the transformer used and the amount of distortion which can be tolerated. The grid bias must be held constant and therefore cannot be obtained by grid leak or series resistor methods. A battery or other source having good regulation is necessary.

The power required of a modulator for complete modulation of a Class C amplifier is one-half the direct power input to the plates of the Class C amplifier.

Radio-Frequency Oscillator or Power Amplifier

Class B—Radio-Frequency Amplifier.

The Class B radio-frequency amplifier is used to amplify a modulated radio-frequency carrier wave without appreciable distortion. It operates similarly to the Class B audio amplifier except that a single tube may be used, the tuned output circuit serving to preserve the wave shape. The push-pull circuit, however, eliminates the even order harmonics and thus increases the efficiency slightly.

Class C—Grid bias below cutoff.

Unmodulated

This type of operation is suitable for telegraphy, or the production of a continuous flow of radio-frequency power for purposes other than communication.

Plate Modulated

This type of operation is for use when the modulating voltage is superimposed on the plate supply voltage and to obtain good quality the output power should vary as the square of the plate voltage. For complete or 100% modulation, the plate voltage varies from zero to twice the applied direct value during a cycle of the audio frequency. With no modulation applied, the plate voltage is, of course, the direct value and the carrier power output is one-fourth of the peak power output under 100% modulation. In this case, since the plate voltage varies with modulation, the direct value must be rated lower than for other types of operation.

High Frequency Ratings

The frequency limits specified under maximum ratings are based on the tube being used as an oscillator. The tube may be used at full rating up to 1.5 megacycles. When operating at higher frequencies, the dielectric losses, charging currents and lead-in heating are increased greatly. The plate voltage and hence plate dissipation must be reduced to values specified for the upper frequency limit and for frequencies between these two limits the plate voltage should be proportionately reduced.

ELECTRON TUBE DATA SHEET WESTERN ELECTRIC 310B ELECTRON TUBE

310B

DESCRIPTION

The 310B is an indirectly heated cathode type pentode having a separate suppressor grid connection. It is intended for use in audio, carrier and radio-frequency voltage amplifiers, oscillators or modulators. This tube, except for having special design features to minimize microphonic noise and hum and having an appreciably lower maximum heater-cathode voltage rating, is identical to the 310A.

Note 1: For optimum tube life, a heater voltage of 9 volts is recommended.
However, when 9 volts is used, it must be regulated to $\pm 1\%$.

Note 2: In the "Absolute System" the maximum ratings specified are limiting values above which the serviceability of the device may be impaired from the viewpoint of life and satisfactory performance. Maximum ratings, as such, do not constitute a set of operating conditions and all values may not, therefore, be attained simultaneously.

TYPICAL CHARACTERISTIC CURVES

These curves are representative of the characteristics of typical tubes when 9.0 volts are applied to the heater. However, these characteristics do not differ significantly when 10.0 volts are applied to the heater.

Vacuum Tube Data

SECTION AB46.595
Issue 1, September 1936
A T & T Co Standard

Western Electric

313A Vacuum Tube

Classification—Double gap, cold cathode, gas-filled tube for use as a relay, rectifier or voltage regulator in special circuits.

The elements of the 313A tube consist of two similar control electrodes and one anode. The conduction path between the control electrodes is known as the control gap. The conduction path between either control electrode and the anode is known as the main gap.

The glass bulb has been given an opaque coating so that the discharge is not visible while the tube is operating. In the photograph at the right the coating has been removed to show the tube elements.

Dimensions—The dimensions and outline diagrams are given in Figs. 1 and 2. The overall dimensions are:

| | | | |
|------------------------|-------|-------|---------------------|
| Maximum length..... | | | 3 $\frac{13}{64}$ " |
| Maximum diameter | | | 1 $\frac{3}{16}$ " |

Mounting—The 313A vacuum tube employs a standard four-pin thrust base suitable for use in a Western Electric 143B or similar socket. The arrangement of electrode connections to the base terminals is shown in Fig. 2.

It may be mounted in either a vertical or horizontal position.

Ratings

| | | |
|--|-------|-----------------|
| Maximum peak control-electrode current..... | | 30 milliamperes |
| Maximum average control-electrode current (averaged over 1 second)..... | | 10 milliamperes |
| Maximum peak reverse current in main gap..... | | 5 milliamperes |

Characteristics

| | |
|--|-----------------------|
| Nominal control gap breakdown voltage | 70 volts |
| Nominal control gap sustaining voltage | 60 volts |
| Nominal main gap breakdown voltage | 175 volts |
| Nominal main gap sustaining voltage | 75 volts |
| Transfer current | 5 microamperes (max.) |
| Nominal deionization time | |
| Main gap | 10 milliseconds |
| Control gap | 3 milliseconds |

The "maximum peak control-electrode current" is the maximum value of current which may be drawn from either control electrode when it is acting as a cathode.

The "maximum average control-electrode current" is the maximum value of current (averaged over 1 second) which may be drawn from either control electrode when it is acting as a cathode.

The "maximum peak reverse current in the main gap" is the maximum value of current which may be drawn from the anode in the reverse direction, that is when it is acting as a cathode. The reverse current rating is intended for use in designing rectifier circuits and is the maximum inverse current which it is permissible to draw from the tube in such circuits.

The "control gap breakdown voltage" is the potential required to initiate ionization, thereby starting conduction in the control gap. Once ionization has occurred the potential across the gap will be reduced to the "control gap sustaining voltage" and will be approximately independent of the current. It is this property of the tube which enables it to be used as a voltage regulator.

The "main gap breakdown voltage" is the potential required to start conduction in the main gap when no ionization is occurring in the control gap. After breakdown, conduction will take place at the "main gap sustaining voltage" and will be practically independent of current.

The "main gap sustaining voltage" is substantially independent of current when the current passes through the tube in the forward direction. When the current passes through the main gap in the reverse direction the sustaining voltage increases rapidly with increasing current. It is this asymmetry in the properties of the main gap of the 313A tube which enable it to be used as a rectifier. The current voltage characteristics of the main gap of a typical 313A tube in both forward and reverse directions as shown in Fig. 3. This curve was obtained with a cathode ray oscilloscope.

When the anode potential is maintained at a value intermediate between the "main gap breakdown and sustaining voltages" the passage of a small amount of current in the control gap will produce ionization sufficient to initiate conduction in the main gap. It is this property of the tube which enables it to be used as a relay. The amount of current in the control gap required to initiate conduction in the main gap is known as the transfer current. This quantity varies considerably from tube to tube and during the life of a given tube but will in general be less than 5 microamperes and usually only a few tenths of a microampere.

The deionization time is the time during which the voltage must be removed from the tube in order that the discharge shall not be reestablished when the voltage is restored. This time increases with increasing applied voltage and with increasing current through the tube before the deionization period. This rate of increase of deionization time is such that the tube will not deionize with a 60 cycle sine wave main gap voltage if the load is inductive or if the peak voltage is near the main gap breakdown voltage or the current near the maximum rated value.

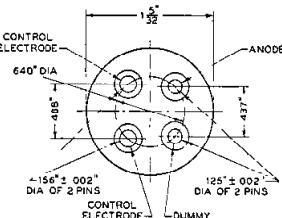

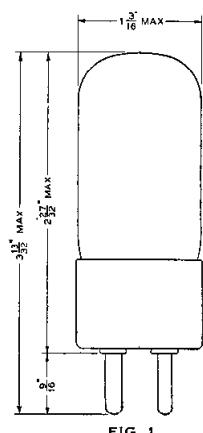

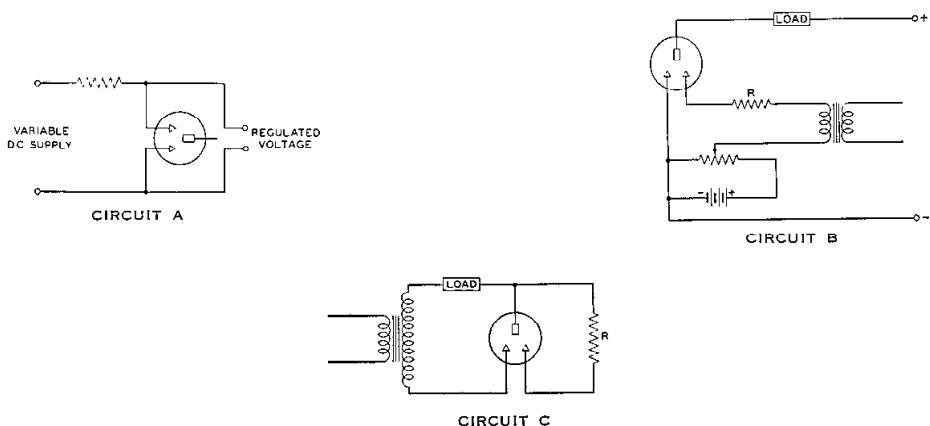

The "transfer time" is the time during which the control gap must be energized in order that the discharge may transfer to the main gap. It depends upon the amount of current flowing in the control gap and on the main gap voltage. For a control gap current of 10 microamperes the "transfer time" is approximately 200 microseconds.

Typical Circuits

Circuit A shows a circuit using the control gap of the 313A as a voltage regulator.

Circuit B shows a circuit using the 313A as a relay. The anode voltage should be intermediate between the main gap breakdown and sustaining voltages and the control anode may be biased at any desired potential less than the control gap sustaining voltage. The resistance R, in the control anode circuit should be of the order of 100,000 ohms. This circuit possesses a "lock-in" feature, since the anode potential must be removed momentarily to restore the tube to a non-conducting condition. When supplied from alternating current this circuit does not possess a "lock-in" feature unless the frequency of the supply voltage is so high that the tube is not allowed a sufficient interval to deionize.

Circuit C shows a circuit using the 313A as a rectifier. The rectifying properties of the main gap are used but the control gap should be connected into the circuit as indicated through a high resistance. This will cause conduction in the forward direction to begin at a voltage much below the main gap breakdown voltage. It is important to note that as a rectifier the 313A tube possesses a unique property not common to other rectifiers in that its impedance is infinite for voltages below the breakdown voltage. In many applications that is of importance since the tube may be used to pass current at the higher potentials without placing a bridge across the line for signals of lower voltage.

HANDLING

This tube contains a small amount of krypton-85 gas which is a by-product radioactive material. The amount of krypton-85 is less than five microcuries, which is too small an amount to require any special care in use.

Atomic Energy Commission regulations require that the individual tube carton for tubes containing by-product radioactive material be appropriately marked. The marking includes the statement that tube disposal should be in approved manner.

Approved instructions for disposal of tubes containing krypton-85 are as follows:

Tubes to be disposed of should be broken or crushed in a well ventilated place releasing any resulting vapors to the outside atmosphere. The residual broken or crushed tubes should be disposed of in a normal public trash disposal system. Tubes should be disposed of at a rate of not more than 100 each week from any one location. Avoid breathing vapors from broken tubes.

Note 1: In the "Absolute System" the maximum ratings specified are limiting values above which the serviceability of the device may be impaired from the viewpoint of life and satisfactory performance. Maximum ratings, as such, do not constitute a set of operating conditions and all values may not, therefore, be attained simultaneously.

Note 2: Sufficient resistance must be used in series with the tube to assure that the electrode currents do not exceed the maximum rated values.

Note 3: Limits apply immediately after tube has conducted current. If tube has been idle, these values initially may be as much as 3 volts higher or lower.

Note 4: With 15 volts overvoltage (15 volts above starter breakdown voltage) with tube in total darkness.

Note 5: Negative anode voltage applied through 8000 ohms. Starter connected to anode through 100,000 ohms.

1. For starting conditions only. Equilibrium operation is limited to +20° minimum condensed mercury temperature.
2. Deionization time decreases with an increase in negative grid voltage or with a decrease in (a) condensed mercury temperature (THg), (b) grid resistance or (c) anode current immediately preceding the end of conduction.
3. Ionization time decreases with an increase in (a) anode voltage, (b) condensed mercury temperature (THg) or (c) grid overvoltage. Grid overvoltage is defined as the magnitude by which the applied voltage exceeds, in a positive direction, the critical grid voltage value. Critical grid voltage is the instantaneous value of grid voltage at the time when anode current starts to flow.

Vacuum Tube Data

SECTION AB46.634
Issue 1, February 1938
A T & T Co Standard

Western Electric

327A Vacuum Tube

Classification—Half-wave, tungsten filament, argon filled rectifier.

The 327A vacuum tube is designed to supply direct current from an alternating-current supply in power systems for battery charging and for other purposes.

Dimensions—The dimensions and outline diagram are given in Figure 1. The overall dimensions are:

| | |
|----------------------------|--------------------|
| Maximum length | 4 $\frac{7}{16}$ " |
| Maximum diameter | 2 $\frac{1}{4}$ " |

Mounting—This tube employs a 3 connection, skirted medium screw base. Overall dimensions are shown in Figure 1.

The tube may be mounted either in a vertical or a horizontal position. There should be a free circulation of air around the tube. No object should touch the glass bulb.

Filament Rating

| | |
|------------------------------------|------------|
| Filament voltage | 2.0 volts |
| Nominal filament current | 12 amperes |

The filament of this tube is designed to operate on a voltage basis from an alternating-current supply. The voltage should be maintained to within 10% of its rated value (2.0 volts). Operation of the filament outside of these limits may cause the tube to become inoperative. Filament and plate voltage may be applied to the tube simultaneously.

Characteristic and Operating Conditions

| | |
|--|-------------------|
| Approximate anode-cathode potential drop | 8 volts |
| Ignition voltage at 60 cycles | 7-16 volts, r-m-s |
| Maximum peak plate current | 6.0 amperes |
| Maximum average plate current | 2.0 amperes |
| Maximum peak inverse potential | 275 volts |

The anode-cathode potential drop is substantially independent of the plate current. The exact value may vary from tube to tube and during the life of a given tube over the range from 5 to 10 volts.

The ignition voltage is the voltage required to start conduction within the tube. In a-c. circuits this is a function of frequency, increasing as the frequency increases. The values are given for 60 cycles since this frequency will be most generally encountered in circuit design.

The maximum permissible peak plate current (6 amperes) is a limitation on the instantaneous value that the tube can carry safely in the direction in which it is designed to conduct and should not be exceeded. The maximum average load current (2 amperes) is the maximum direct output current which may be obtained from a half-wave circuit using one tube. A full-wave circuit using two tubes will supply a maximum of 4 amperes.

The maximum permissible peak inverse potential (275 volts) is a limitation on the instantaneous value that the tube can stand safely. If it is exceeded, an arc-back may result which may injure the tube. All circuits should be adequately fused to prevent injury to the equipment in event of arc-back due to line surges. The maximum output voltage obtainable in either the half-wave or full-wave circuit is approximately 75 volts.

327A vacuum tubes may be operated in parallel if some provision is made to insure a proper division of the load current. Current dividing reactors or ballasting resistors in series with each anode, may be used for this purpose. The size of the reactors or resistors depends upon the circuit design.

Western Electric

328A Vacuum Tube

Classification—Voltage-amplifier, suppressor-grid pentode with indirectly heated cathode

The electrical characteristics of the 328A tube are identical with those of the 310A tube except for the heater voltage and current.

This tube is intended primarily for use in audio, carrier and radio-frequency voltage amplifiers, oscillators or modulators. The connection for the suppressor grid has been brought out to an external terminal, thus making the tube more flexible in its applications.

Dimensions—Dimensions, outline diagrams of the tube and base, and the arrangement of the electrode connections to the base terminals are shown in Figures 1 and 2.

Base—Small, six-pin thrust type with pins silver-plated. A small, metal cap control-grid terminal is located at the top of the bulb.

Socket—Standard, six-contact type, preferably provided with silver-plated contacts such as the Western Electric 144B socket.

Mounting Positions—This tube may be mounted in any position.

| Suppressor grid to heater, cathode and screen grid | 7.5 | $14.5 \mu\text{f}$ |

Column A—Without shield.

Column B—With close-fitting metal shield connected to cathode.

Heater Rating

| | |
|----------------------------------|-------------------------|
| Heater voltage | 7.5 volts, a.c. or d.c. |
| Nominal heater current | 0.425 ampere |

The heater element of this tube is designed to operate on a voltage basis and should be operated at as near the rated voltage as is practicable.

Cathode Connection—Preferably direct to the heater. If voltage must be applied between the cathode and heater, it should not exceed 150 volts.

Characteristics—Plate current and screen-grid current characteristics of a typical 328A tube are shown in Figures 3 and 4, respectively, as functions of control-grid voltage for several values of screen-grid and plate voltage and zero suppressor-grid voltage. The screen-grid voltage for these characteristics is equal to the plate voltage. Corresponding amplification factor, plate resistance, and transconductance characteristics are given in Figures 5, 6 and 7. Plate current and screen-grid current characteristics as functions of plate voltage are given in Figures 8 and 9, respectively, for several values of control-grid voltage, a screen-grid voltage of 135 volts, and zero suppressor-grid voltage. Corresponding amplification factor, plate resistance, and transconductance characteristics are shown in Figures 10, 11 and 12. Plate current, screen-grid current, plate resistance, and transconductance characteristics are shown in Figures 13, 14, 15 and 16 as functions of plate voltage for several values of suppressor-grid voltage, a screen-grid voltage of 135 volts, and a control-grid voltage of -3 volts. These last characteristics are of particular interest in modulator applications where separate inputs are applied to the control and suppressor grids.

Limiting Conditions for Safe Operation

| | |
|--|------------------|
| Maximum plate voltage | 250 volts |
| Maximum screen-grid voltage | 180 volts |
| Maximum cathode current (screen-grid current plus plate current) | 10 milliamperes |
| Maximum screen-grid current | 2.5 milliamperes |

Operating Conditions and Output—Nominal performance data are given in the table below for a number of typical operating conditions. Less severe operating conditions should be selected in preference to maximum operating conditions wherever possible. The life of the tube at maximum conditions may be shorter than at less severe conditions.

The performance data include the fundamental voltage or power output for the indicated values of load resistance and input voltage, and the maximum second and third harmonic levels for input voltages no greater than the indicated values. The voltage output is given in peak volts, the power output in milliwatts, and the harmonic levels in decibels below the fundamental.

TABLE

| Plate-Voltage Volts | Screen-Grid Voltage Volts | Control-Grid Bias Volts | Suppressor-Grid Voltage Volts | Plate Current Milliamperes | Load Resistance Ohms | Input Voltage Peak Volts | Output Voltage Peak Volts | Output Power Milliwatts | Second Harmonic db | Third Harmonic db |

ELECTRON TUBE DATA SHEET
WESTERN ELECTRIC 328A ELECTRON TUBE

328A

DESCRIPTION

The 328A is an indirectly heated cathode type pentode having a separate suppressor grid connection. It is intended for use in audio, carrier and radio-frequency voltage amplifiers, oscillators or modulators. This tube, except for having a different heater voltage and current rating, is identical to the 310A tube.

CHARACTERISTICS

SECTION AB46.585
Issue 1, August 1939
A T & T Co Standard

Western Electric

311A and 329A Vacuum Tubes

Classification—Low-power, suppressor-grid pentodes with indirectly heated cathodes

The 311A and 329A tubes are identical except for the heaters.

These tubes are intended primarily for use as audio, carrier or radio-frequency power amplifiers where power outputs of approximately two watts are required and where the plate voltage is not in excess of 180 volts. The suppressor grid is permanently connected to the cathode within the tube.

Dimensions and Connections—Dimensions, outline diagrams of the tubes and bases, and the arrangement of the electrode connections to the base terminals are shown in Figures 1 and 2.

Base and Mounting—These vacuum tubes employ small five-pin thrust type bases with silver plated pins. They are adapted for use in standard five-contact type sockets, preferably those provided with silver-plated contacts such as the Western Electric 141A socket. A small metal cap control-grid terminal is located at the top of the bulb.

The tubes may be mounted in any position.

Average Direct Interelectrode Capacitances

| | <u>A</u> | <u>B</u> |
|---|----------|------------------|
| Control grid to plate | 0.29 | 0.07 $\mu\mu$ f. |
| Control grid to heater, cathode and screen grid | 8 | 9 $\mu\mu$ f. |
| Plate to heater, cathode and screen grid | 9 | 12 $\mu\mu$ f. |

Column A—Without shield.

Column B—With close fitting metal shield connected to the cathode.

Heater Ratings

| | <u>311A Tube</u> | <u>329A Tube</u> |
|----------------------------------|------------------|-------------------------|
| Heater voltage | 10.0 | 7.5 volts, a.c. or d.c. |
| Nominal heater current | 0.64 | 0.85 ampere |

The heaters should be operated on a voltage basis and at as near the rated voltage as practicable.

The voltage between the cathode and the heater should not exceed 150 volts.

Characteristics—Figures 3 and 4 respectively, show plate current and screen-grid current as functions of control-grid voltage for several values of screen and plate voltage. In all curves the plate voltage is equal to the screen voltage. Amplification factor, plate resistance and transconductance curves for the conditions corresponding to those of Figures 3 and 4 are given respectively in Figures 5, 6 and 7.

Plate current and screen-grid current are shown as functions of plate voltage in Figures 8 and 9 respectively, for a screen-grid voltage of 135 volts and for several values of control-grid voltage. Corresponding curves for amplification factor, plate resistance and transconductance are given in Figures 10, 11 and 12 respectively.

Curves showing the fundamental power output and the second and third harmonic levels as functions of input voltage for a number of values of load resistance for typical operating conditions are given in Figures 13, 14 and 15 respectively.

Limiting Conditions for Safe Operation

| | |
|--|-----------------|
| Maximum direct plate voltage | 180 volts |
| Maximum direct screen-grid voltage | 150 volts |
| Maximum cathode current (plate current plus screen-grid current) | 60 milliamperes |
| Maximum direct screen-grid current | 12 milliamperes |

Operating Conditions and Output—Nominal performance data are given in the table on page 3 for a number of typical operating conditions. Less severe operating conditions should be selected in preference to the maximum conditions wherever possible. The life of the tube at maximum conditions will be shorter than at the less severe conditions.

The performance data include the fundamental power output for the indicated values of load resistance and input voltage, and the maximum second and third harmonic levels for input voltages not exceeding the indicated values. Under certain conditions the maximum second harmonic level occurs at a lower input voltage than that given in the table. The power output is given in watts, and the harmonic levels in decibels below the fundamental.

Western Electric

338A Vacuum Tube

ONLY

Classification—Three element, argon filled, thyatron, with an indirectly heated cathode

It is primarily a rectifier of low internal impedance whose conduction cycle is determined by the relative instantaneous grid and anode potentials. It is intended for use in special circuits as a relay or trigger-action device. A few of its other possible uses are: as a controlled-frequency oscillator giving a square wave form, as a voltmeter or volume level-indicator, as a source of sweep-voltage for a linear time axis, or as a variable-voltage rectifier.

Dimensions—The dimensions and outline diagrams are given in Figures 1 and 2. The overall dimensions are:

Maximum length $4\frac{7}{16}$ "

Diameter $1\frac{1}{16}$ "

Mounting—This vacuum tube employs a standard five-pin thrust type base suitable for use in a Western Electric 141A or similar socket. The arrangement of electrode connections to the base terminals is shown in Figure 2.

It may be mounted in either a vertical or horizontal position, although the vertical position is preferable.

FILE: THYRATRON SECTION

Heater Rating

| | |
|-----------------------------|------------|
| Heater potential..... | 10.0 volts |
| Nominal heater current..... | 0.5 ampere |
| Required heating time..... | 60 seconds |

The heater element of this tube is designed to operate on a voltage basis from a direct or alternating current supply. The voltage should be maintained to within 5% of its rated value (10 volts). Operation of the heater element above the upper limit will definitely reduce the life of the tube, while a decrease below the lower limit may cause immediate failure.

Sufficient time should always be allowed for the cathode temperature to reach its normal operating value before anode current is drawn. Failure to allow sufficient time may result in immediate failure.

Operating Conditions

| | |
|--|-------------------|
| Approximate tube voltage drop | 15 volts |
| Max. peak voltage between anode and grid | 325 volts |
| Max. instantaneous anode current ... | 0.600 ampere |
| Max. average anode current | 0.100 ampere |
| Max. time of averaging anode current..... | 5 seconds |
| Max. instantaneous grid current..... | 0.010 ampere |
| Max. voltage between heater and cathode. | 50 volts |
| Operating ambient temperature range..... | -20° to +50°C. |
| Normal deionization time..... | 1000 microseconds |

The characteristics of the 338A tube are such that, for any given anode potential, there is a critical grid potential. If the grid is held more negative than this value and the tube is non-conducting, the anode current will remain zero. If it is made less negative, the current will assume a value determined by the applied potential and the resistance in the anode circuit. To extinguish the discharge and return the current to zero, the positive anode potential must be removed. When current is flowing a visible discharge occurs in the tube. Under this condition, the tube voltage drop is practically independent of the value of both the anode current and the grid potential. A protective resistance should always be included in the circuit to limit the anode current to the rated values. A typical curve relating the critical grid potential to the anode potential is shown in Figure 3. This characteristic may vary from tube to tube and during the life of a given tube.

Sufficient resistance must always be included in the grid circuit to limit the negative grid potential to 10 volts when anode current is flowing. Failure to observe this precaution will result in short tube life.

Typical Circuits

The tube may be used in a variety of circuits adapted to the application of thyratrons. Two general types are common. One use of the tube is to produce a saw-toothed, current wave. The circuit for this application is shown in Figure 4. The resistance R should, ordinarily, be at least 100,000 ohms, and the product RC (C in farads) approximately equal to the desired fundamental period.

The second general use for the tube is as a relay device. In this application the anode may be supplied from either alternating or direct current. When supplied from direct current, the circuit, Figure 5, possesses a "lock-in" feature, since the anode potential must be removed momentarily in order to restore the tube to the non-conducting condition. When supplied from alternating current, the circuit possesses no "lock-in" feature, but the average anode current may be controlled by the relative phase of grid and anode potentials. The schematic circuit for this application is shown in Figure 6. Figure 7 is a simplified circuit employing a photoelectric cell in place of the resistance, R, used in the phase shifting device in Figure 6. The photoelectric cell, however, is equivalent to a variable resistance in the sense that the current passed will depend upon the amount of light falling upon it.

RECTIFIER

FULL-WAVE, HIGH VACUUM

Western Electric

DESCRIPTION

The 345A is a full-wave rectifier with indirectly heated cathodes. It is designed to supply direct current from an alternating current source or to rectify radio-frequency currents for feedback purposes in broadcast transmitters.

CHARACTERISTICS

| | |
|---------------------------------------|------------------|
| Heater Voltage | 6.3 volts |
| Maximum Plate Voltage (RMS) per Plate | 400 volts |
| Maximum D-C Output Current | 100 milliamperes |

GENERAL CHARACTERISTICS

ELECTRICAL DATA

Dimensions and pin connections shown in outline drawing on page 4

- Note 1: Sufficient resistance must be used in series with the tube to assure that the electrode currents do not exceed their maximum rated values.
- Note 2: Limits apply immediately after tube has conducted current. If the tube has been idle, these values initially may be as much as 3 volts higher or lower.
- Note 3: With 15 volts starter overvoltage (15 volts above Starter Breakdown Voltage) with tube in total darkness.
- Note 4: Negative anode voltage applied through 8000 ohms. Starter connected to anode through 100000 ohms.

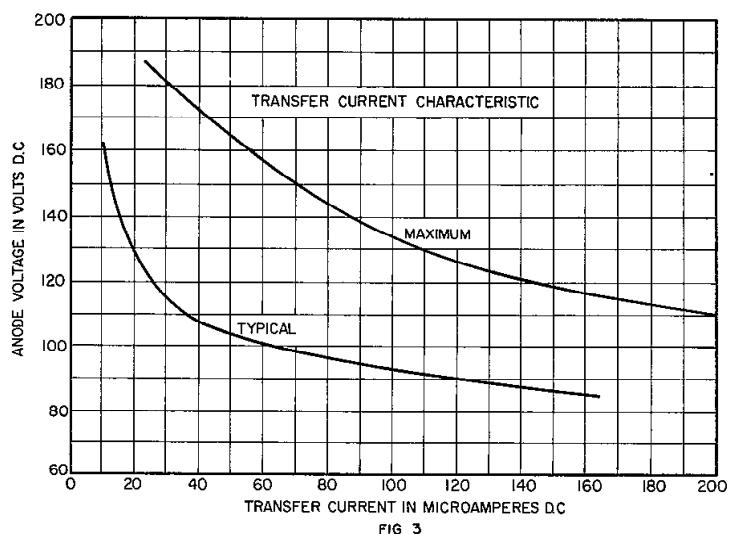

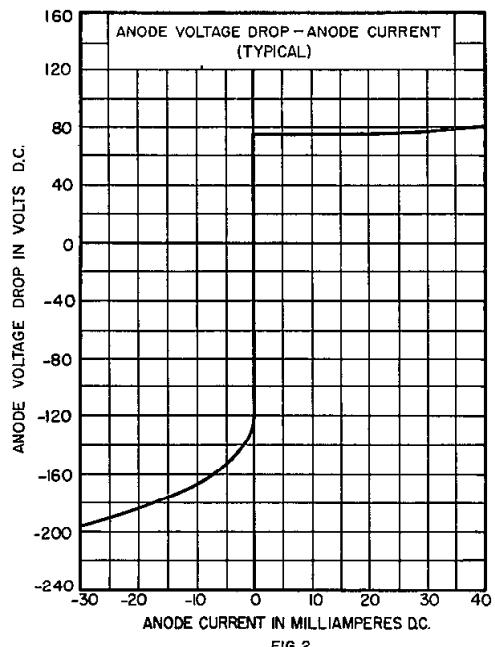

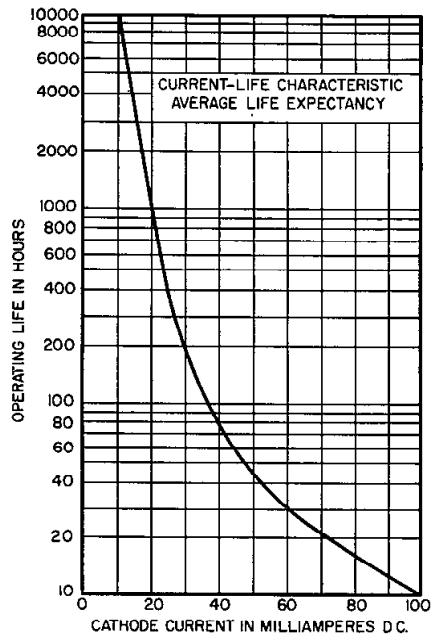

HANDLING

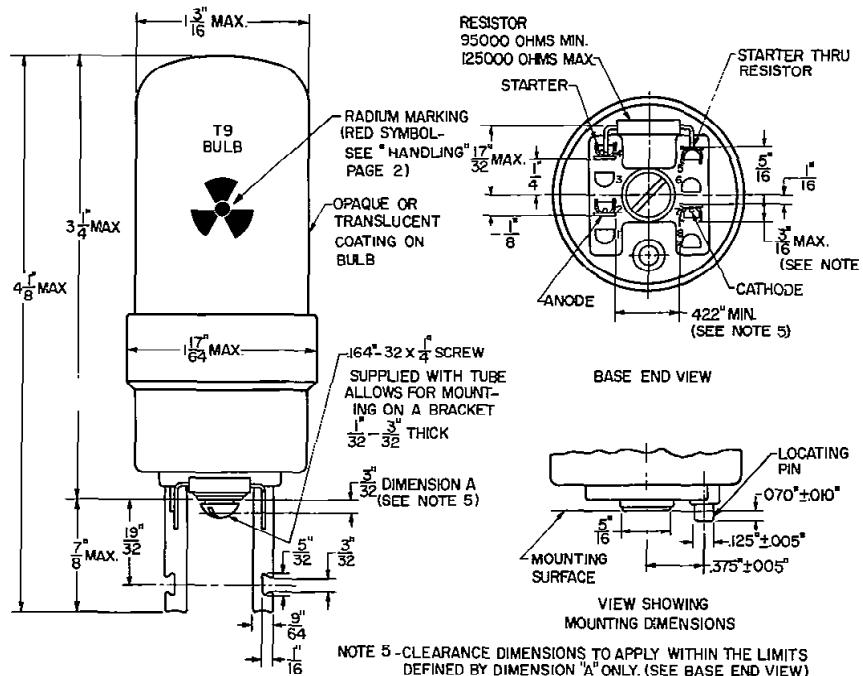

Western Electric cold cathode tubes contain a minute amount of radium bromide which is a radioactive material. The amount in most types is too small to require any special care in use, handling or disposal.

A few types contain a larger quantity of radium bromide in which the radium approximates that found on a luminous watch dial. These types bear a red three-bladed propeller-shaped symbol on the tube envelope. Instructions for handling such tubes are given below and also in Bell System Practices for Central Office maintenance.

Installations ordinarily require no precautions against radiation. However, quantities of the tubes should not be so installed, or so stored outside the shipping carton, that they will be within a few inches of personnel or in proximity to photographic film for extended periods of time. For example, however, a 40-hour week exposure at about one (1) foot from a bank of 500 tubes (covering an area of 20 inches x 45 inches) is well within the accepted tolerance limits for personnel. Reasonable care should be exercised in handling and disposal of broken tubes. In general, attention should be given to the following:

- (a) Avoid breathing dust or vapors from broken tubes.
- (b) Avoid contacting broken parts with bare hands.
- (c) Use wet rag to pick up broken parts. Wrap broken parts in rag and tie securely so as to form a package. Thoroughly wash hands after disposal.
- (d) Dispose of broken or defective tubes as they are taken out of service. One or two tubes at a time may be disposed of with normal waste material. Accumulation of tubes in one concentrated area of the place of final disposition should be avoided.

HANDLING

This tube contains a small amount of krypton-85 gas which is a by-product radioactive material. The amount of krypton-85 is less than five microcuries, which is too small an amount to require any special care in use.

Atomic Energy Commission regulations require that the individual tube carton for tubes containing by-product radioactive material be appropriately marked. The marking includes the statement that tube disposal should be in approved manner.

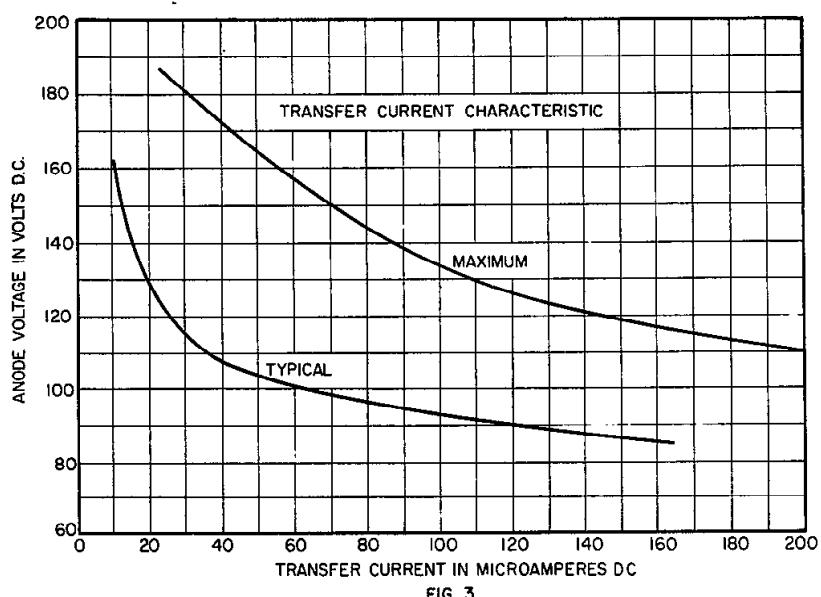

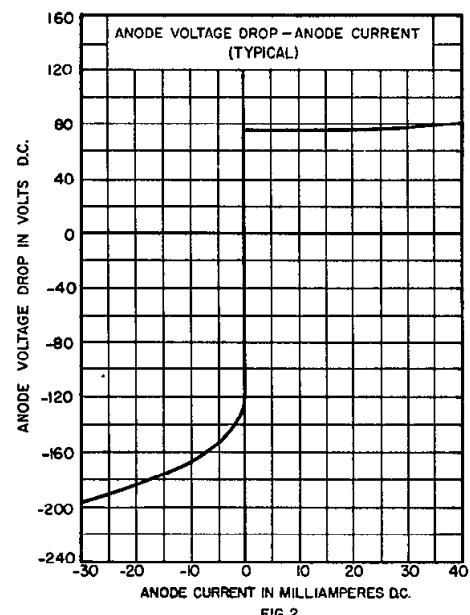

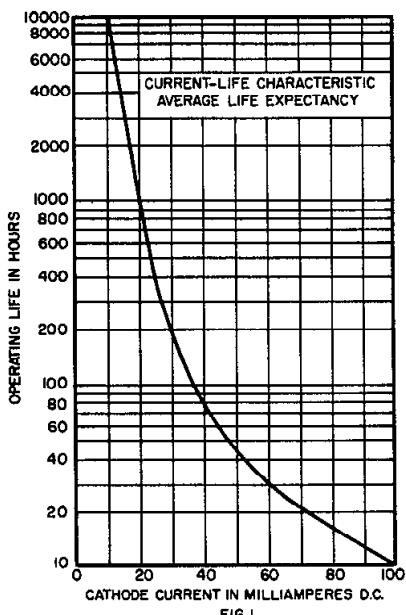

Approved instructions for disposal of tubes containing krypton-85 are as follows:

Tubes to be disposed of should be broken or crushed in a well ventilated place releasing any resulting vapors to the outside atmosphere. The residual broken or crushed tubes should be disposed of in a normal public trash disposal system. Tubes should be disposed of at a rate of not more than 100 each week from any one location. Avoid breathing vapors from broken tubes.

Note 1: In the "Absolute System" the maximum ratings specified are limiting values above which the serviceability of the device may be impaired from the viewpoint of life and satisfactory performance. Maximum ratings, as such, do not constitute a set of operating conditions and all values may not, therefore, be attained simultaneously.

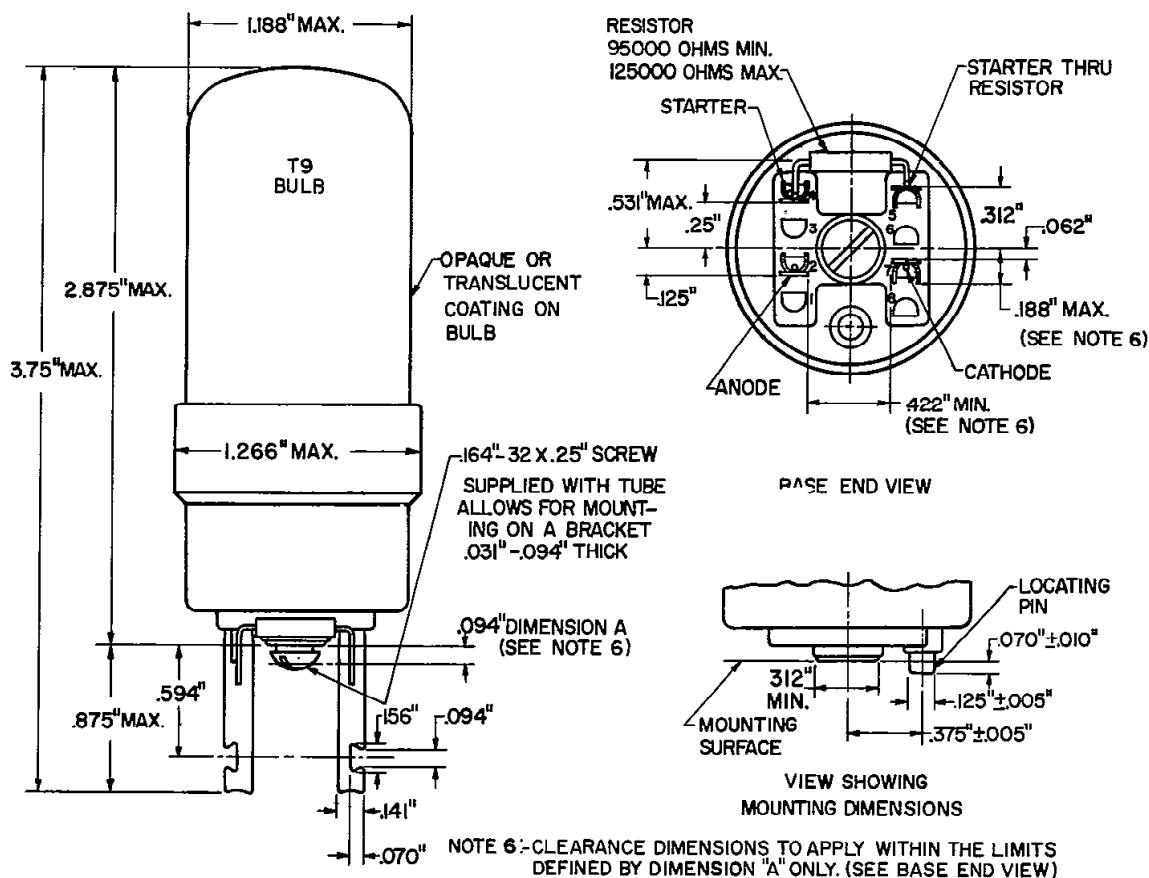

Note 2: Sufficient resistance must be used in series with the tube to assure that the electrode currents do not exceed their maximum rated values.

Note 3: Limits apply immediately after tube has conducted current. If the tube has been idle, these values initially may be as much as 3 volts higher or lower.

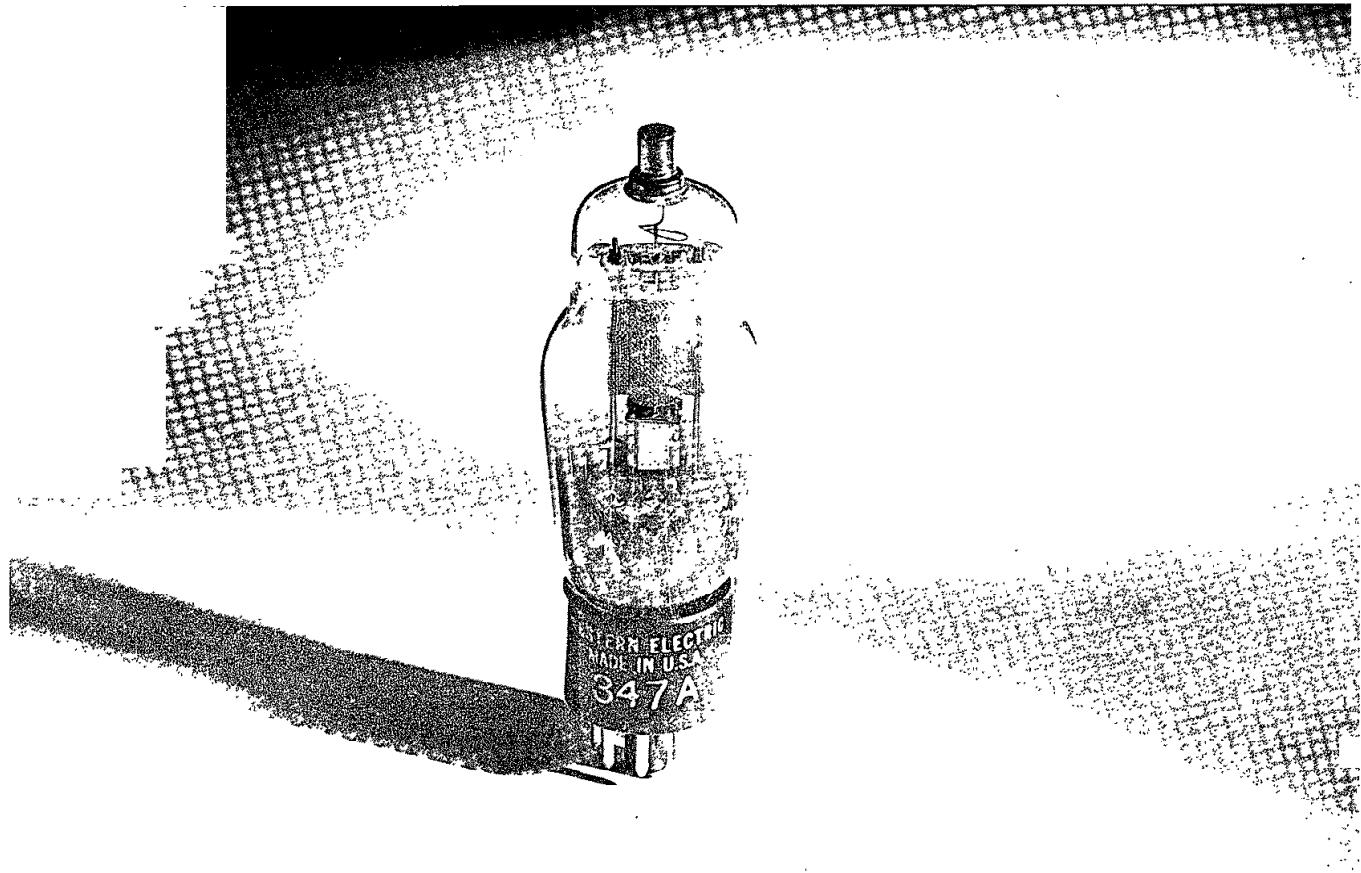

Note 4: With 15 volts starter overvoltage (15 volts above Starter Breakdown Voltage) with tube in total darkness.

Note 5: Negative anode voltage applied through 8000 ohms. Starter connected to anode through 100,000 ohms.

HUM

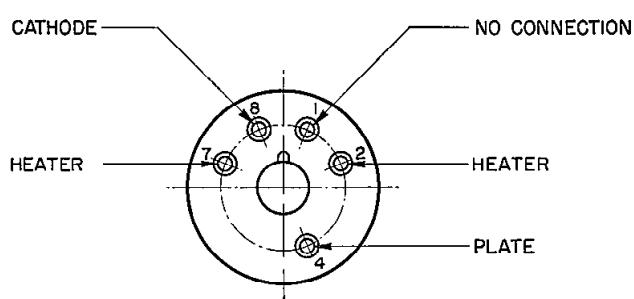

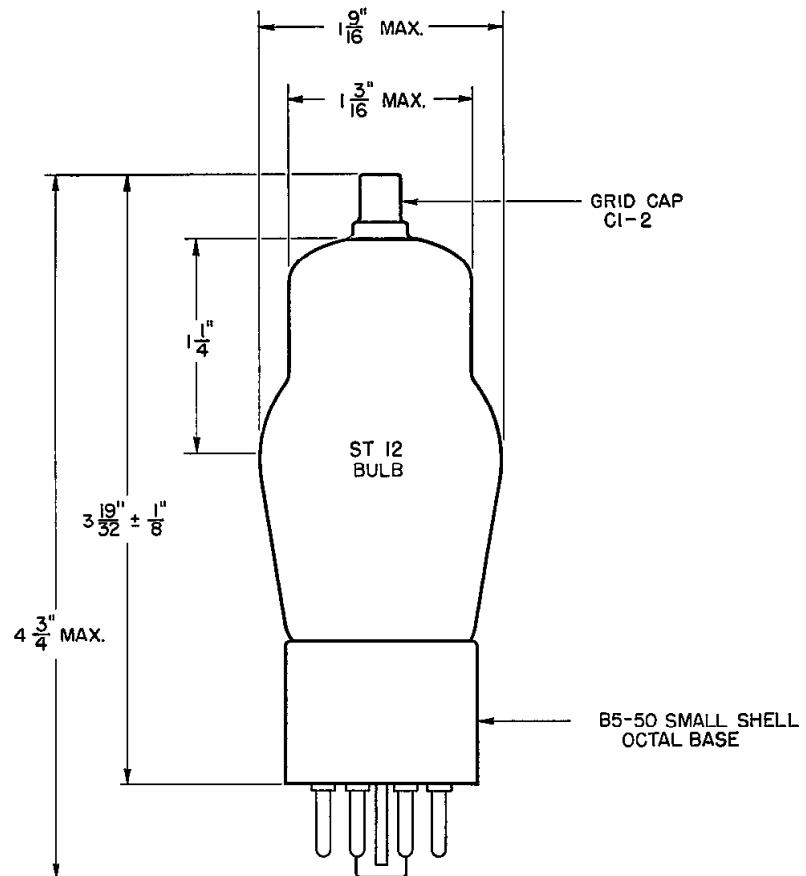

Under typical operating conditions, and with the cathode of the tube connected to the mid-point of the heater circuit, the equivalent hum voltage in the grid circuit will be less than 12 microvolts at the supply frequency and less than 6.0 microvolts at

double the supply frequency.

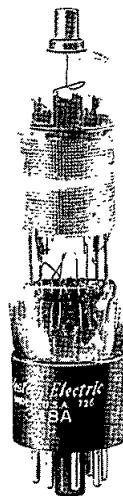

If the insulation leakage and capacitance between the external grid and heater connections are kept reasonably low, a resistance of 2 megohms may be used in the grid circuit without materially affecting the hum level.

ELECTRON TUBE DATA SHEET WESTERN ELECTRIC 348A ELECTRON TUBE

348A

DESCRIPTION

The 348A is an indirectly heated cathode type pentode having a separate suppressor grid connection. It is intended for use in audio, carrier and radio-frequency voltage amplifiers, oscillators or modulators. It has special design features to minimize microphonic noise and hum. This tube, except for having a different base, top cap, heater voltage and current rating, is identical to the 31OB.

350B

TETRODE
BEAM POWER AMPLIFIER

Western Electric

DESCRIPTION

The 350B is a beam power tetrode of the neuter-cathode type. It is designed for use as an audio-frequency amplifier or as a radio-frequency oscillator.

CHARACTERISTICS

| | |
|----------------------------|-----------------|
| Heater Voltage | 6.3 volts |
| Plate Current | 93 milliamperes |
| Transconductance | 8300 micromhos |
| Power Output | 10.5 watts |

Plate Current $E_b = E_{c2} = 250$ volts;
Transconductance $E_{c1} = -14$ volts

GENERAL CHARACTERISTICS

ELECTRICAL DATA

| | |
|--|-------------|
| Heater Voltage, A-C or D-C | 6.3 volts |
| Heater Current | 1.6 amperes |

RECTIFIER
FULL-WAVE, HIGH VACUUM

Western Electric

DESCRIPTION

The 351A is an octal based full-wave rectifier with indirectly heated cathodes. It is designed to supply direct current from an alternating current source or to rectify radio-frequency currents for feedback purposes in broadcast transmitters.

CHARACTERISTICS

| | |
|---------------------------------------|------------------|
| Heater Voltage | 6.3 volts |
| Maximum Plate Voltage (RMS) per Plate | 400 volts |
| Maximum D-C Output Current | 100 milliamperes |

GENERAL CHARACTERISTICS

ELECTRICAL DATA

| | |
|----------------|------------|
| Heater Voltage | 6.3 volts |
| Heater Current | 1.0 ampere |

MECHANICAL DATA

| | |

352A Vacuum Tube

•

Classification—Duodiode triode with an indirectly heated cathode

The 352A tube comprises three distinct vacuum tube units which are independent of each other except that sections of a single cathode structure supply electron emission for all three. Two of these units are diodes. The other is a triode.

Applications—Diode detector, diode rectifier for automatic volume control voltage, and triode audio-frequency amplifier. If desired the two diodes may be used for full-wave rectification or they may be connected in parallel to provide a lower impedance half-wave rectifier. The former connection requires about twice as high an input voltage as the latter to give equal detector output.

Dimensions and Connections—Outline diagrams of the tube and base giving the dimensions and the arrangement of the electrode connections to the base terminals are shown in Figures 1 and 2.

Base and Mounting—This tube employs a small six-pin thrust type base suitable for use in a Western Electric 144B or similar socket. The base pins are silver plated. The triode grid terminal is a small metal cap located at the top of the bulb.

This tube may be mounted in any position.

Average Direct Interelectrode Capacitances

| | | |
|---|-------|------------|
| Triode grid to plate..... | 1.5 | $\mu\mu f$ |
| Triode grid to cathode and heater..... | 1.6 | $\mu\mu f$ |
| Triode plate to cathode and heater..... | 3.8 | $\mu\mu f$ |
| Both diodes to triode grid | 0.015 | $\mu\mu f$ |
| Both diodes to triode plate..... | 1.4 | $\mu\mu f$ |
| Both diodes to cathode and heater..... | 6.5 | $\mu\mu f$ |

Heater Rating

| | | |
|-----------------------------|------|---------------------|
| Heater voltage | 10.0 | volts, a.c. or d.c. |
| Nominal heater current..... | 0.32 | ampere |

The heater of this tube is designed to operate on a voltage basis and should be operated at as near the rated voltage as practicable.

Cathode Connection—Where alternating heater voltage is used the cathode should preferably be connected directly to the mid-point of the heater transformer winding or to the mid-point of a low resistance connected across the heater terminals. For direct current operation the cathode may be connected to either end of the heater. If voltage is applied between the heater and cathode, it should be kept low and must not exceed 50 volts.

Triode Characteristics—Typical curves showing triode plate current as a function of grid voltage for several values of plate voltage are shown in Figure 3. Corresponding amplification factor, plate resistance and transconductance characteristics are given in Figures 4, 5 and 6 respectively. Figure 7 shows plate current as a function of plate voltage for several values of grid voltage.

Triode Operating Conditions and Output

Permissible operating plate and grid voltages are included within the area, ABCD, in Figure 3. Amplification factor, plate resistance, transconductance and performance data for a number of typical operating conditions are given in the table. Recommended conditions or others of no greater severity should be selected in preference to maximum conditions wherever possible. The life of the tube at maximum operating conditions will be shorter than at less severe conditions.

In the last four columns of the table are given the fundamental power output, P_m , in milliwatts, the fundamental voltage output, E_{pm} , in peak volts and the second and third harmonic levels, F_{2m} and F_{3m} , in db below the fundamental, for the indicated values of load resistance. The peak value of the sinusoidal input voltage, E_{gm} , is numerically equal to the grid bias in each case. Where the level of the third harmonic is lower than 45 db below the fundamental, its value may be widely different from tube to tube. The values given represent a typical tube.

For a smaller input voltage, E_g , the fundamental power and voltage outputs and the harmonic levels are given approximately by the following relations:

$$P = P_m \left(\frac{E_g}{E_{gm}} \right)^2$$

$$E_p = E_{pm} \frac{E_g}{E_{gm}}$$

$$F_2 = F_{2m} + 20 \log_{10} \frac{E_{gm}}{E_g}$$

$$F_3 = F_{3m} + 40 \log_{10} \frac{E_{gm}}{E_g}$$

*Maximum operating conditions.

Triode Microphonic Noise—With a plate voltage of 135 volts, a grid bias of -6 volts, and a load resistance of 100,000 ohms, the mean microphonic noise output level of the triode section of the tube, measured in a laboratory reference test set, is 45 db below 1 volt. The range of levels of individual tubes extends from 20 to 60 db below 1 volt. Since microphonic noise depends on the type and intensity of the mechanical disturbance which produces it, the values given here are useful chiefly for comparison with the levels of other tubes which have been tested in the same way.

Diode Characteristics—The current-voltage characteristic of a single diode is shown in Figure 8. Rectification characteristics for a single diode are shown in Figure 9 for a number of values of impressed alternating input voltage. Each of these characteristic curves gives the relation between the direct voltage impressed on the diode plate and the average diode current as indicated by a direct-current microammeter for a constant impressed alternating input voltage of the value specified. Where the diode is used as a detector with the usual condenser-resistance circuit, the direct component of the voltage developed across the resistance by any alternating-voltage input is given by the intercept of the load line with the rectification characteristic corresponding to the input voltage. Load lines for zero fixed bias are shown in Figure 9 for load resistance values of 0.25, 0.5 and 1.0 megohm.

The potential of each diode plate with respect to the cathode on the positive swing of the input voltage should be limited to a maximum value of +10 volts.

HANDLING

This tube contains a small amount of krypton-85 gas which is a by-product radioactive material. The amount of krypton-85 is less than five microcuries, which is too small an amount to require any special care in use.

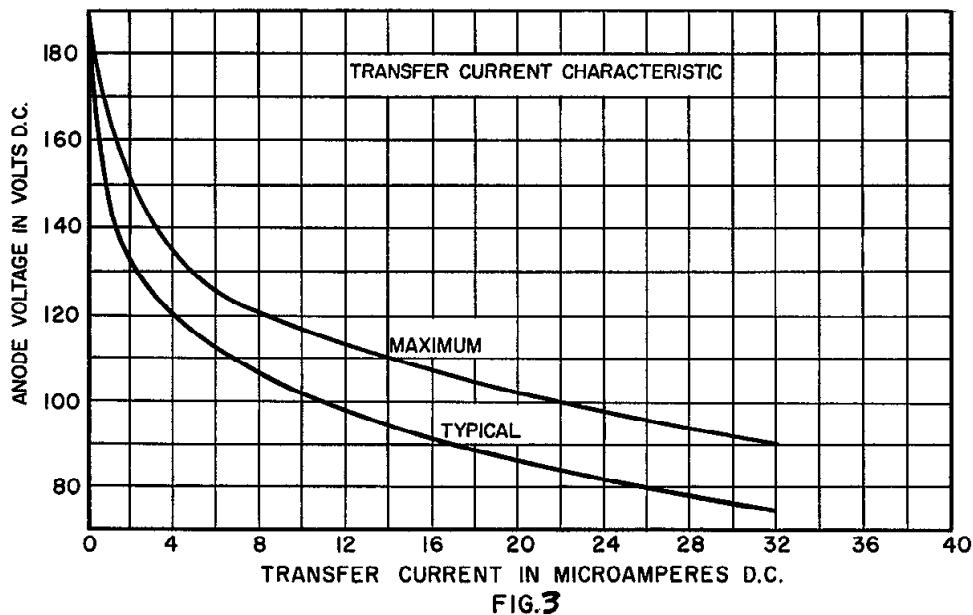

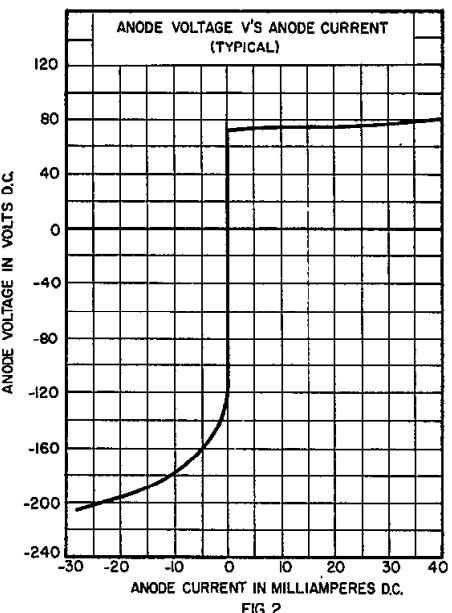

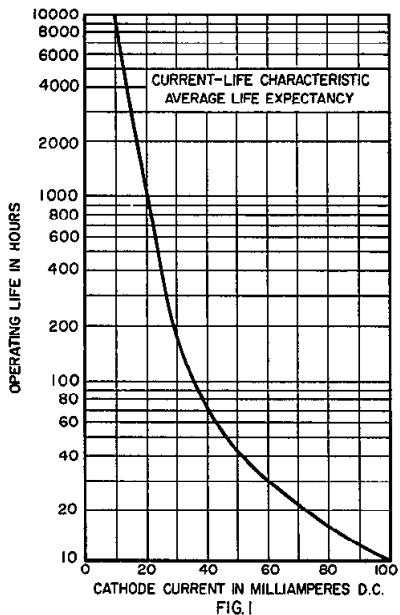

Atomic Energy Commission regulations require that the individual tube carton for tubes containing by-product radioactive material be appropriately marked. The marking includes the statement that tube disposal should be in approved manner.

Approved instructions for disposal of tubes containing krypton-85 are as follows:

Tubes to be disposed of should be broken or crushed in a well ventilated place releasing any resulting vapors to the outside atmosphere. The residual broken or crushed tubes should be disposed of in a normal public trash disposal system. Tubes should be disposed of at a rate of not more than 100 each week from any one location. Avoid breathing vapors from broken tubes.

Note 1: In the "Absolute System" the maximum ratings specified are limiting values above which the serviceability of the device may be impaired from the viewpoint of life and satisfactory performance. Maximum ratings, as such, do not constitute a set of operating conditions and all values may not, therefore, be attained simultaneously.

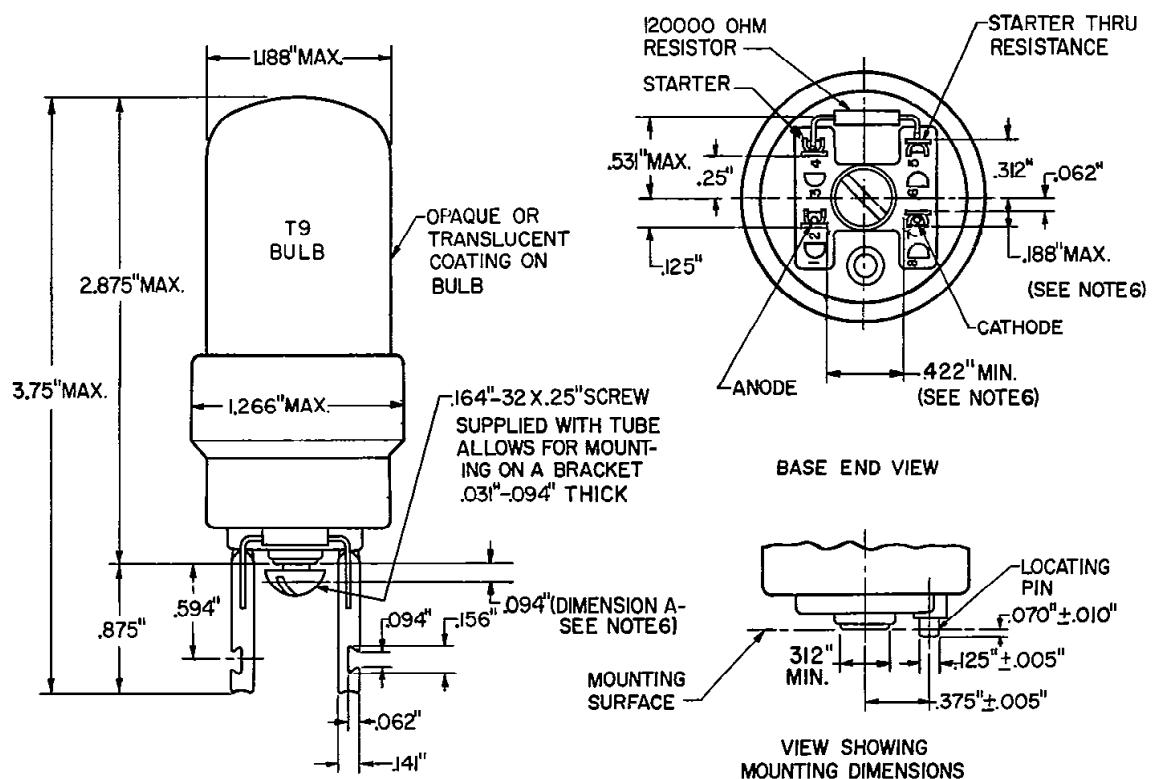

Note 2: Sufficient resistance must be used in series with the tube to assure that the electrode currents do not exceed the maximum rated values.

Note 3: Limits apply immediately after the tube has conducted current. If tube has been idle, these values initially may be as much as 3 volts higher or lower.

Note 4: With 15 volts starter overvoltage (15 volts above starter breakdown voltage) with tube in total darkness.

Note 5: Negative anode voltage applied through 8000 ohms. Starter connected to anode through 100,000 ohms.

NOTE 6 - CLEARANCE DIMENSIONS TO APPLY WITHIN THE LIMITS
DEFINED BY DIMENSION "A" ONLY. (SEE BASE END VIEW)

1. Deionization time decreases with an increase in negative grid voltage or with a decrease in (a) condensed mercury temperature (THg), (b) grid resistance or (c) anode current immediately preceding the end of conduction.
2. Ionization time decreases with an increase in (a) anode voltage, (b) condensed mercury temperature (THg) or (c) grid overvoltage. Grid overvoltage is defined as the magnitude by which the applied voltage exceeds, in a positive direction, the critical grid voltage value. Critical grid voltage is the instantaneous value of grid voltage at the time when anode current starts to flow.

1. For starting conditions only. Equilibrium operation is limited to +20C minimum condensed mercury temperature.
2. Deionization time decreases with an increase in negative grid voltage or with a decrease in (a) condensed mercury temperature (THg), (b) grid resistance or (c) anode current immediately preceding the end of conduction.
3. Ionization time decreases with an increase in (a) anode voltage, (b) condensed mercury temperature (THg) or (c) grid overvoltage. Grid overvoltage is defined as the magnitude by which the applied voltage exceeds, in a positive direction, the critical grid voltage value. Critical grid voltage is the instantaneous value of grid voltage at the time when anode current starts to flow.

357B

**TRIODE
AMPLIFIER, OSCILLATOR OR MODULATOR**

Western Electric

DESCRIPTION

The 357B is a three-electrode tube designed for use as a radio-frequency amplifier or oscillator, audio-frequency amplifier or modulator. The anode is capable of dissipating 400 watts. The tube is cooled by radiation at frequencies below 40 megacycles.

Forced-air cooling of the envelope is necessary at higher frequencies. The tube is capable of operating up to 100 megacycles at maximum ratings and up to 150 megacycles at reduced ratings. The cathode is a thoriated tungsten filament.

1. Represents maximum usable cathode current for tube as plate current plus grid current for any condition of operation.

2. Radiation cooling is adequate when the tube is operated below 40 megacycles and with a free circulation of air around the tube. If operated in a confined space or at a frequency above 40 megacycles, forced-air cooling is necessary. Satisfactory air cooling will be obtained from a blower delivering approximately 40 cubic feet of air per minute from a 2-inch diameter nozzle. The nozzle outlet should be placed approximately 3 inches from the

tube and directed toward the central point of the envelope, midway between the plate and grid terminals.

The plate terminal connector shall be of a design that will readily conduct heat from the plate terminal.

3. This test is equivalent to a JAN-1A Pendulum Bump Tester 15° test. The data given represent the maximum capabilities of the tube without electrical potentials applied and should not be construed to mean that the tube is capable of withstanding an infinite number of shocks of this magnitude.

ELECTRON TUBE DATA SHEET
WESTERN ELECTRIC 358A ELECTRON TUBE

358A

DESCRIPTION

The 358A is a two-electrode, inert-gas-filled, cold cathode tube designed to provide a visual signal for telephone work. When the tube is conducting, a glow will appear near the surface of the negative electrode. If a d.c. voltage supply is used the negative polarity should be applied to the upper electrode. The upper electrode terminal may be identified by the adjacent circular dot of contrasting color on the base. When the tube is operating with an alternating voltage a glow will appear on both electrodes.

APPLICATION DATA

This tube possesses a unique property not common to filamentary type lamps in that its impedance is essentially infinite for voltages below breakdown. In some applications this is an advantageous feature since the tube may be used to pass current at the higher potentials without placing a conducting path across the line for signals of lower voltage.

Unlike filamentary type lamps the light output of this tube is proportional to the current through the tube instead of varying as a power of this current. This tube is well adapted to furnishing a visual signal from a varying voltage source.

Note 1: In the "Absolute System" the maximum ratings specified are limiting values above which the serviceability of the device may be impaired from the viewpoint of life and satisfactory performance. Maximum ratings, as such, do not constitute a set of operating conditions and all values may not, therefore, be attained simultaneously.

Note 2: When the tube is operating from a direct current supply, the upper electrode shall be used as the cathode.

HANDLING

This tube contains a small amount of krypton-85 gas which is a by-product radioactive material. The amount of krypton-85 is less than five microcuries, which is too small an amount to require any special care in use.

Atomic Energy Commission regulations require that the individual tube carton for tubes containing by-product radioactive material be appropriately marked. The marking includes the statement that tube disposal should be in approved manner.

Approved instructions for disposal of tubes containing krypton-85 are as follows;

Tubes to be disposed of should be broken or crushed in a well ventilated place releasing any resulting vapors to the outside atmosphere. The residual broken or crushed tubes should be disposed of in a normal public trash disposal system. Tubes should be disposed of at a rate of not more than 100 each week from any one location. Avoid breathing vapors from broken tubes.

ELECTRON TUBE DATA SHEET
WESTERN ELECTRIC 359A ELECTRON TUBE

359A

DESCRIPTION

The 359A is a three-electrode, inert-gas-filled, cold cathode tube for use primarily as a relay in communication circuits. It is also suitable for use in control circuits such as in triggering, counting or switching apparatus and as a visual indicator. This tube, by reason of small size and provision for wiring directly into the circuits, may be used to advantage in equipment having limited space for components.
