POWER MODULE.

Due to the high power level required on the output load, the amplifier final stage's structure differs from the design used until now. This is due to the breakdown voltage limit on P-channel MosFET's, with is 200V. This final stage is formed by several shunted MosFET's, where those of the positive branch are common-drain configured, and the negative branch are mounted in common-source configuration.

The system's controlling device is a NE5534-type operational amplifier, with is internally compensated in order to obtain gain levels equal or higher than three. The amplifier's feedback is given by a resistor and a capacitor associated to the operational amplifier's non inverting input.

Transistors BF471 and BF472 are common-base configured, forming a current supply structure. This specific transistor type is used because of the higher Vce voltage level required by this design. They perform simultaneously two functions: they polarize the MosFET's gate-source junctions, keeping them on the conducting edge, and they transfer the OpAmp's output voltage variations referred to signal ground.

The signal variations normally reflected by Q107 and referred to the positive power supply, are now needed to be floating variations, and referred to the outputs. This function is done by Q109-110 (BF472), with are mounted forming a Wilson-type mirror current supply. This mirror current supply transfers all of the current variations detected while descending through Q109's collector, to similar variations on Q110's collector also downward current. Resistors R167 and R174 are used to balance the current mirror, in order to avoid the use of transistors with forcibly the same beta value. C138 and C141 suppress their resistance when high frequency signal is processed. Diodes D126 and D127 avoid the transistors to get saturated, and R171 eliminates the loads on BF472's bases (Baker Circuit).

The system requires about 12Vdc additional voltage upon the usual Vcc level, this allows a correct saturation and a symmetric clipping at the higher MosFET's.

The correct polarization current value is adjusted by a 4K7 potentiometer connected to the BF transistor's emitter. This adds an additional current to the current source output on the BF transistor's loading resistors.

In order to maintain the appropriate stand-by current level against varying temperature conditions, BD437-type transistors are used. As they have a particular temperature-depending base-emitter voltage curve, this voltage is used to keep a correct voltage reference for the current supply. As the temperature rises, the reference voltage level decreases, the gate-source voltage also decreases and, finally, the bias current also decreases.

Transistors Q111 and Q112, and their corresponding twins at the lower branch, form a current-buffering circuit with allows a fast charge and discharge of the power MosFET's gates.

The Zobel circuit, a resistance-capacitance-inductance formed network associated to the amplifier's output, tries to keep the amplifier's output load impedance constant no matter with load value is connected to the output, or with frequency is processed, in order to avoid phase shifts on the feedback signal.

To avoid the presence of DC voltage on the output, a diac-triac based system is used, with shorts the output to signal ground in case the DC level reaches the diac's triggering value. To avoid this to happen when processing correct signal (sine waveform, music...), the diac obtains its reference level from a filtering network formed by a 100K resistor and a 1 μ F capacitor.

The protections circuitry overhauls the MosFET's power consumption. Basically, this circuitry consists of two important sections: MosFET's Id current monitoring, and MosFET's Vds value detection.

When the MosFET's Id level rises above a certain level, transistor Q119 (controlling transistor) conducts and decreases the BF transistor's loading resistance, thus reducing also their gate-source voltage and, finally, lowering the Id current value. This system is helped by a delayed performance, due to the associated circuitry to Q145 and C174. This capacitor starts to charge when a current level above the allowed value is detected, and the protection starts. The greater is the capacitor's charge level, the higher is also the voltage applied to Q119 controlling transistor's base, increasing its conduction and, consequently, reducing the gate-source voltage and thus the Id current value. This system uses a feedback network. The delay used is necessary to avoid clipping the processed signal's dynamic range, with should result in the typical clipping noise. In the negative branch, the protection circuitry is associated to control transistor Q120.

In case the overcurrent is not occasional, and persists, after a period of time between 4 and 10 seconds (determined by R142 and C124), the system switches back to Stand-by mode, due to a system-reset. This is done by an optocoupler (IC113) associated to the negative branch protection circuitry. When protections get activated, IC113 gradually charges C124 until a 40106-type Schmidt trigger gate switches over. If the problem persists, this cycle is repeated.

STANDBY CIRCUITRY. This circuit maintains the Output shutdown relay closed for about 10 seconds, and thus annulated any current through the MosFET's during this period, just until the whole system's power supply voltage reaches its stable level. By this system, we avoid to hear through the loudspeakers any possible annoying noise proceeding from the system's start-up.

This delay time is achieved by using a RC cell, where $R135=287K$ and $C119=47\mu F/50V$. As this cell charges, its voltage increases until reaching the 40106-type Schmidt trigger (IC108) switching value; at this point, the relay opens and the amplifier starts to function normally.

The discharge or reset of capacitor $C119=47\mu F$ can be done by cutting off the power supply, or by triggering the Thermal or other protections. During a short period of time, BC817-type transistor Q102 acts like a switch, shunting two 75Ω resistors to C119.

Moreover, the amplifier includes some other additional features, like:

- Volume control by a VCA system.
- An ANTICLIP system.
- A Temperature control system.

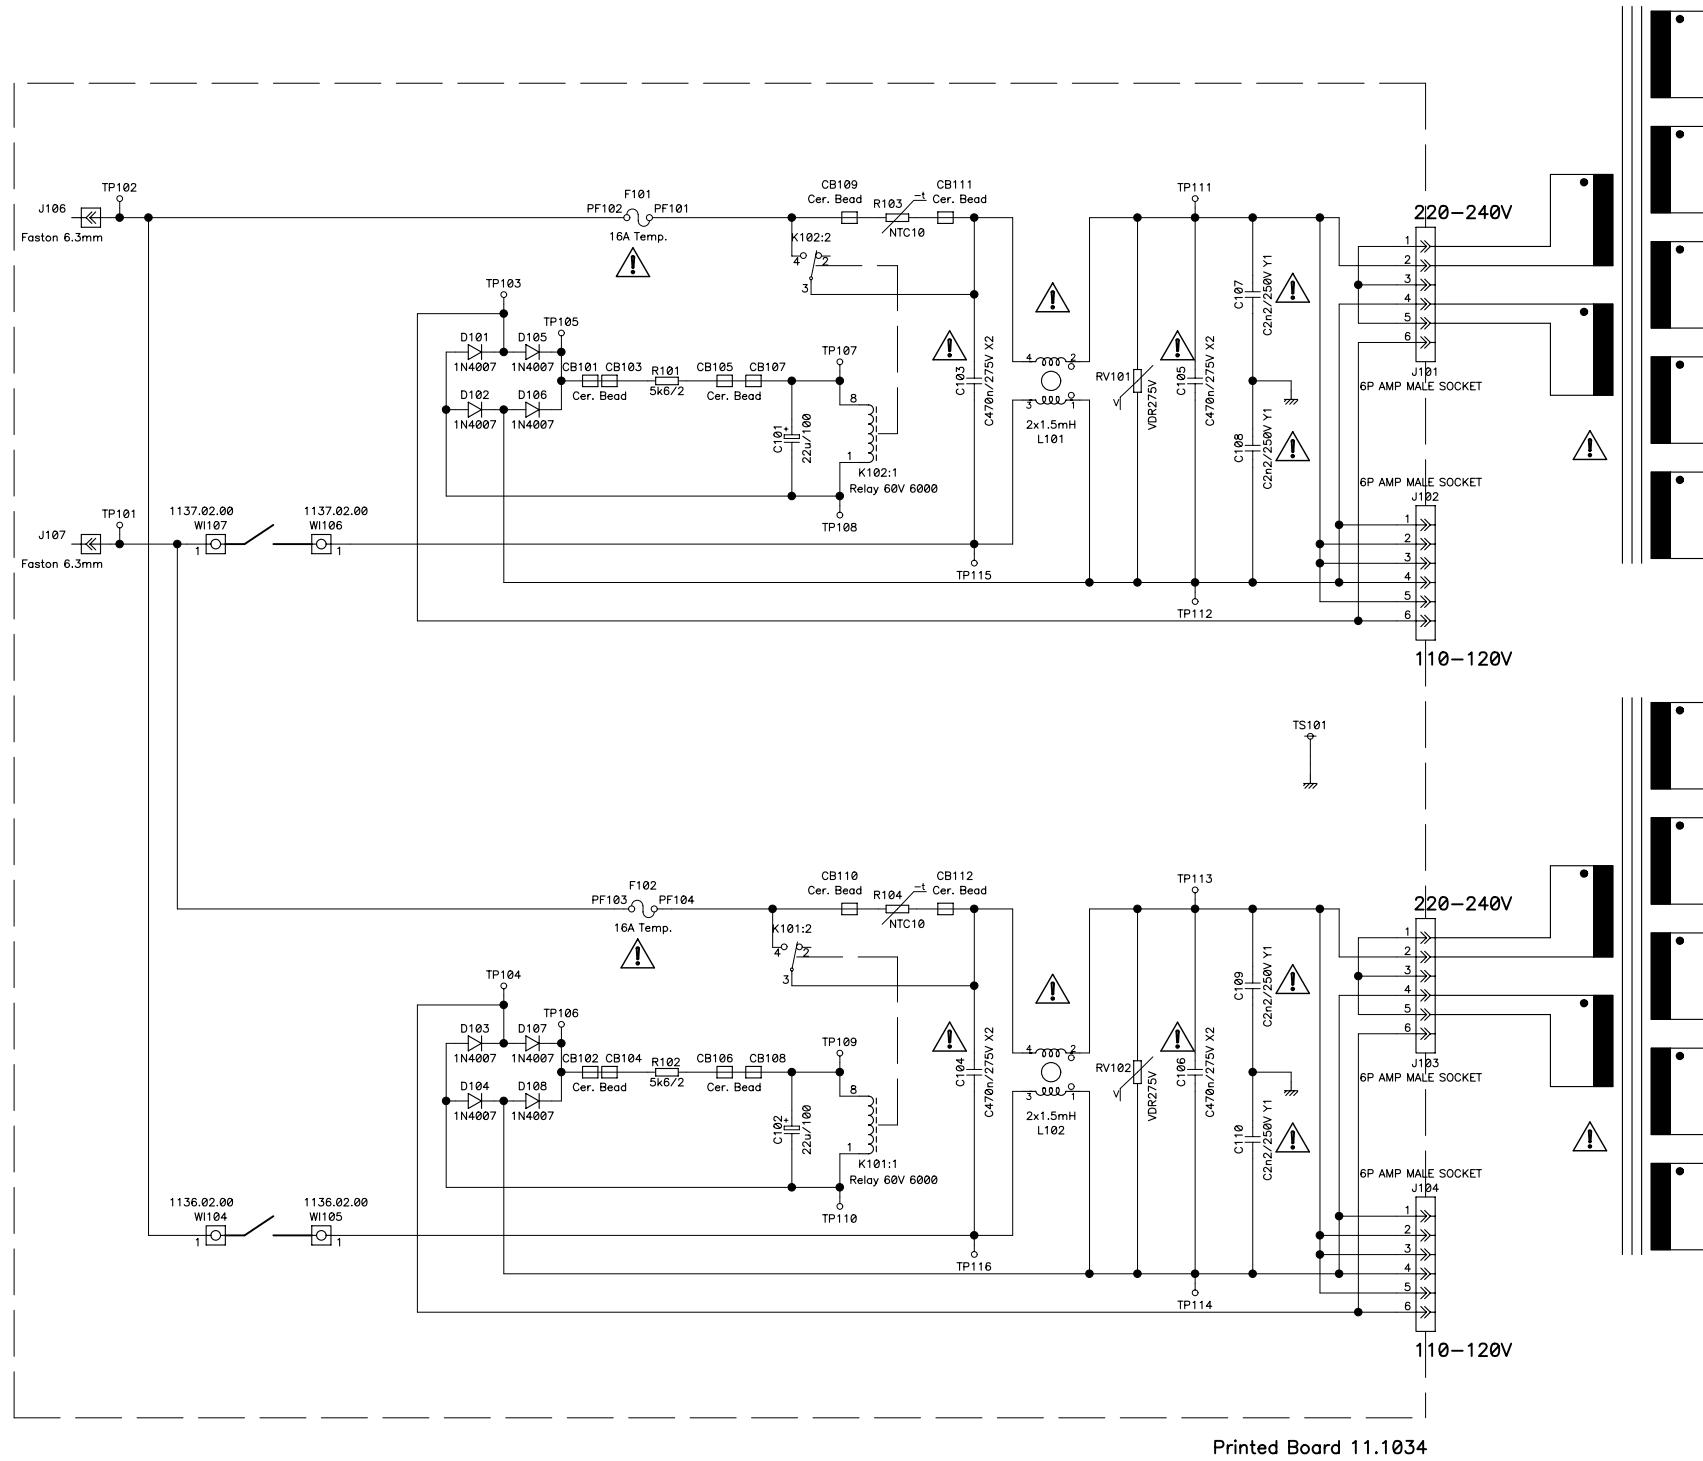

THE ANTICLIP SYSTEM. When the amplifier reaches clipping levels, the operational amplifier loses control on the system's performance and at its output some $\pm V_{cc}$ voltage peaking pulses may appear, proceeding from its power supply. These peaking pulses are used to be rectified and sent to an optocoupler (IC111), which varies the system's VCA control voltage as a function of those pulse's amplitude, creating a negative feedback which should pull back the system into stable functioning area.

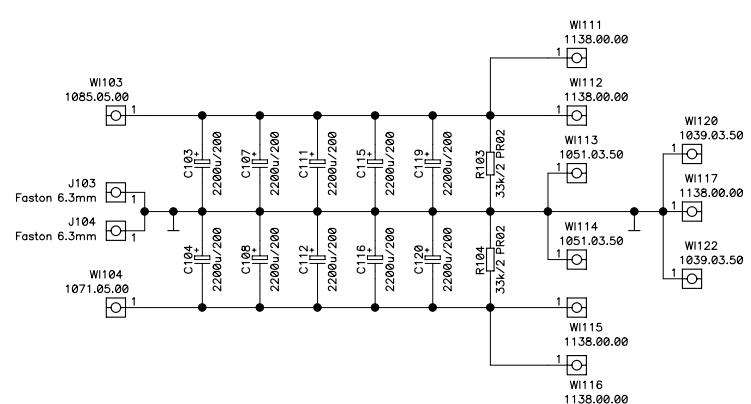

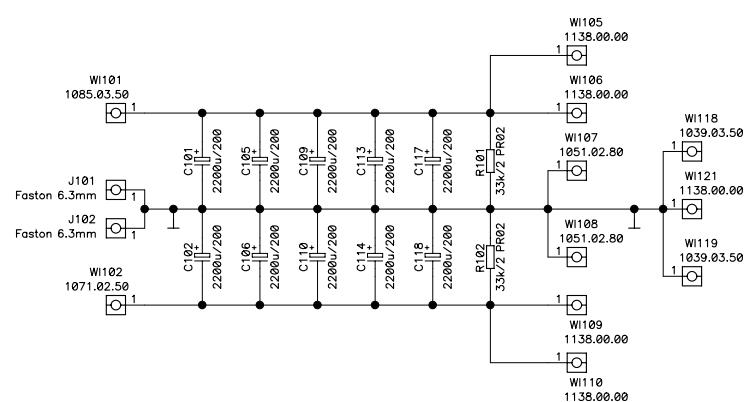

The Temperature control system has three main functions:

- Controlling the cooling fan speed, as it is a function of the measured temperature. The fan's operation voltage range is 7 to 14 Volts.
- Suspending the amplifier's functioning when the temperature exceeds $92^\circ C$
- Reducing the amount of power output, depending on the module's temperature (as it rises above $85^\circ C$) and on the main power supply's transformer (above $120^\circ C$).

The temperature control system consists on two LM35D-type IC's, which act like a thermal probe; one is placed on the amplifier's heat sink, and the other is placed into the main power supply transformer's core. Moreover, three amplifiers, a comparator for the thermal probe and a 7805-type IC to feed the cooling fan are used.

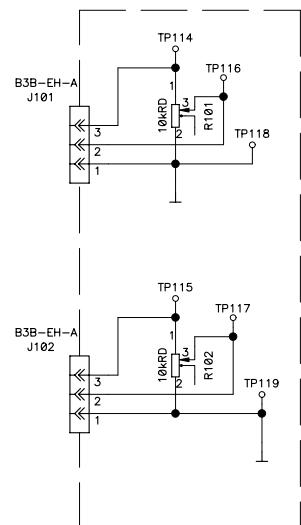

The first amplifier (1/4 IC114) acts on the cooling fan speed control. The second amplifier (1/4 IC114) modifies the VCA gain control, in order to reduce the system's gain if the temperature rises above $85^\circ C$. The third amplifier (1/4 IC114) modifies the VCA gain control, in order to reduce the system's gain if the temperature rises above $120^\circ C$. The comparator (1/4 IC114) is responsible for the output shutdown relay performance, in order to close it as the temperature reaches $92^\circ C$, and thus cutting off the amplifier's MosFETs bias current. As this happens, the signal output of the whole unit is cut off.

Assembled Amplifier.

PRELIMINARY:

- Set the BRIDGE-STEREO selection switch to STEREO.
- Check the *Ground Link* switch.
- Keep the subsonic filter, at the input stage circuitry, set to OFF.
- Be sure that the correct cable types are used.
- Connect the power amplifier mains plug to a 230Vac variac output, and leave it on its 0V position.
- Keep an ammeter nearby (DC 10A range), in order to verify the current consumption adjustments.

VERIFICATION:

- Switch the tested unit's Power main switch to ON, without applying any input signal.
- Remove the protection fuse of the positive power supply, and place instead a 10A DC ranged ammeter. Keep the module's output signal insight by using an oscilloscope, selecting a 10V/div vertical scale and 5ms/div time base. **Note:** In case of doubt, if you only want to feed one channel while verifying the current consumption, simply do not insert the mains protection fuse in the other channel.
- Slowly increase the variac's output until it reaches the unit's nominal mains voltage, and if an excessive current consumption is detected (current flow above 800mA), stop the testing procedure immediately and try to identify the failure. Once the nominal mains voltage is reached, wait for a minute and verify that the current consumption adjustments remain correct: 300mA for DPA4000T, 190mA for DPA2500T. If these values have changed, rectify them. Once adjusted, seal the potentiometer with fixing lacquer.

Caution! The unit's power supply will be charged! Before removing the ammeter and replacing the fuse, it is strongly recommended to completely discharge the unit's power supply by applying a 1KHz 0dB input signal and connecting 4Ω load impedances to the amplifier's output, and reduce the unit's mains voltage to 0V by turning down the variac's output.

- Repeat this procedure on the other channel.
- Once the adjustments are done, turn on again the unit by switching over its main power switch, and verify the STANDBY period lasts approximately 10 seconds, the *clip* and *protect* indicating LED's light up, and also the cooling fans run up to their maximum running speed.
- Verify both XLR-type inputs, the *STK-OUTPUT*, their correspondent *signal present* indicator LED's and also check the correct functioning of the input signal attenuators, as their actuation range.
- Verify the unit's output power when working at nominal mains voltage (230Vac):

DPA4000T	1880W	86,7V on 4Ω
DPA2500T	1130W	67,2V on 4Ω

- To verify the ANTICLIP function, increase the input signal level above 0dB and check that the clipping output signal is smoothed. Check the CLIP indicator LED's are lit, and, when reducing the output signal level in 0,5 or 1dB, the CLIP LEDs turn off.
- Verify the unit's bandwidth curve, with a 2KHz 0,5V input signal, should be linear between 20Hz and 20KHz without inducing any distortion to the output signal. Also check that when applying an input signal up to 50KHz, the unit's output level only decreases in 1 or 2dB, and no visible distortion is observed.
- Verify the BRIDGE operating mode. Switch over the BRIDGE-STEREO selector to BRIDGE, check that both channels are achieving the same gain level when not loaded. In order to verify this, apply a 1KHz 0dB input signal to channel I and, with the volume potentiometer turned up to its maximum,

check with a millivoltmeter that at TP102 a 0dB gain level is obtained. If not, adjust R125. Once channel I is fixed to 0dB, verify TP102 at channel II and proceed to adjust if gain level is not 0dB.

- Connect a 8Ω load impedance to the speakon-type BRIDGED output, and verify the achieved output power levels:

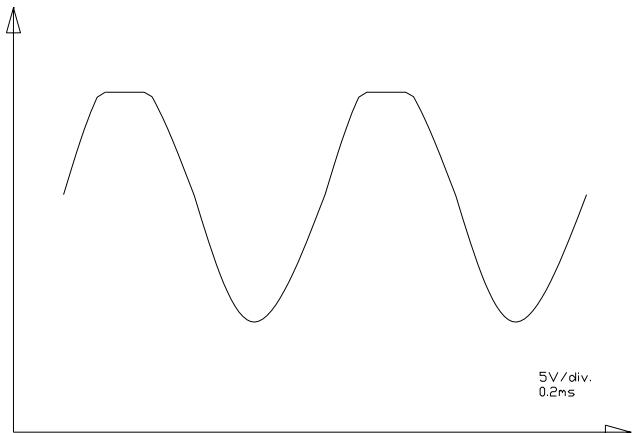

3760W	173,4V	for DPA4000T
2260W	134,5V	for DPA2500T

Only channel I's input potentiometer should be active. Verify that the amplifier reaches its clipping state without troubles. Return the unit to its STEREO operating mode.

- Connect a load impedance formed by a 4Ω resistor shunted to a $2\mu F$ capacitor, and apply a 1KHz square waveform input signal. Using an oscilloscope, observe the output signal, and increase the input signal level until the displayed signal starts clipping. At the flat level areas of the squared waveform, only two or three ringing should be detected.
- Verify the SUBSONIC FILTER. Check the amplifier's output level at 25Hz, is reduced in 4,5dB when comparing with the measured level without subsonic filtering. Leave the filter on the ON position.
- Verify the THERMAL protection circuitry. Short the LM35D thermal probe pins 1 and 2, and verify that the relay releases and closes, while the *THERMAL* and *PROTECT* LEDs indicators light up, as the output signal is cutted off and the cooling fan increases its speed until it reaches maximum airflow.
- Repeat this procedure on the other module.

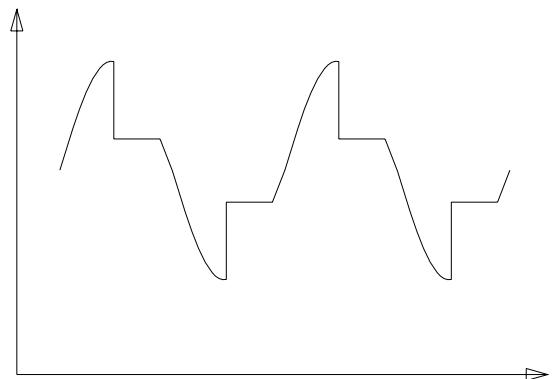

PROTECTIONS

- Adjust the signal generator to deliver a 1KHz 0'8Vrms signal, and leave it ON.
- Turn down the power stage volume potentiometer to its minimum.
- Connect a $0,5\Omega$ load impedance.
- Connect the oscilloscope test probes parallel to the load impedance. Select a 5V/div vertical scale, and a 0'2ms/div time base.
- Turn up quickly the volume potentiometer. Depending on which branch is working, the positive or negative half of the signal cycle is clipped. Verify that no ringing appear when the protection is triggered.
- The output signal should be somehow similar to the picture shown in the figure (from 15Vpp to 20Vpp). There are two protection circuitries, one on the positive and another on the negative branches of the unit. In case one of this protections does not actuate properly, the output signal will appear completely asymmetric. The level of the half-cycle which is not being protected will not be limited, thus allowing to find out which branch is failing. It could also happen that none of the protections are triggered, this can be detected as the measured signal levels delivered to the load impedance are not being compressed. In case this happens, immediately stop the testing procedure. This may occur when the unit is receiving too low mains voltage (at least 240V, 250V recommended), or if the signal level is increased too slowly through the potentiometer.
- After a period between 5 and 10 seconds is elapsed since the protection circuitry has triggered, the module should switch over into PROTECT operating mode. This is, the relay closes, the PROTECT indicator LED lights up, output signal is cutted off, and the 10 seconds lasting STANDBY cycle is started.
- Wait until the STANDBY cycle ends, and allow the unit to repeat the process.
- Turn off the signal generator, output level set to minimum.

DC OUT

- In order to run this test, do not connect any load impedance.
- Adjust the signal generator to deliver a signal with a frequency below 5Hz, and select the 3V scale output level.
- Connect the oscilloscope to the unit's output, 5V/div vertical scale, 20ms/div time base. Use a 10x attenuating test probe.
- Turn on the signal generator. Increase its output level until the thyristor starts actuating, and the observed signal becomes the typical sawed sine wave. Use the oscilloscope's memory bank in order to observe carefully this fact.

VERIFICATION USING MUSIC

Verify the unit's sound quality, which should be distortion- and noise-free. Once the unit is turned on and its STANDBY cycle time has elapsed, the output relays release, but no annoying noise is heard through the loudspeakers. Also check that all potentiometers can run smoothly their whole sweep, without noise and crispings. At their minimum position, check that output signal is completely cut off. To ensure that all electrical junctions are well-fixed, hit the tested unit against your working table, obviously without damaging its outer presentation. Verify all in- and outputs. Short the output terminals while carrying amplified signal, wait approximately 5 or 10 seconds, after which the unit should perform a general reset. Verify the PROTECT indicating LED lights up, the output signal is cut off, and the STANDBY cycle is correctly done. Once the short-circuit is removed, the unit recovers normal functioning.

QUALITY CONTROL

All mechanical parts should be visually revised, in order to detect scratches on the unit's painting; all screws should be on their place, correctly tight and unmarked. Check out the unit's general presentation.
