

**Service manual**  
**DN60/RT60**  
**Spectrum analyser**

## GENERAL DESCRIPTION

The intention of this section is to provide a basic understanding of how the DN60 operates.

In essence the function of an audio spectrum analyser is to separate the components of any audible signal into defined frequency bands, and to indicate the level of energy present in each of those bands. A frequency analysis given by the DN60 displays the overall energy level of a signal and where that energy is distributed through the audio spectrum (in frequency bands of 1/3 octaves) in a bar graph format.

NOTE: Since frequency analysis represents the separate components of the overall signal, it follows that the "overall-level" displayed should be equal to the sum of the individual components.

The following description will be clarified by reference to the block diagram fig. 1.

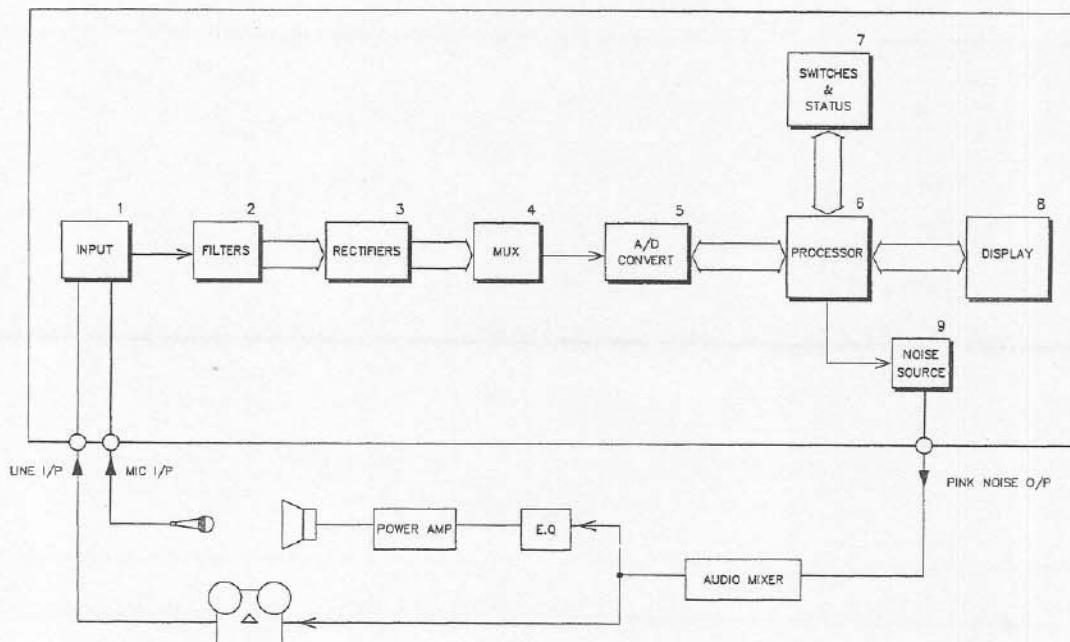

Figure 1.

In order to make a valid analysis of any system a reference signal source is required. This is fed into the system under test and the output compared to it. Most suitable for the purpose is 'Pink Noise'.

By definition Pink Noise consists of all frequency components (in the audio band) randomly produced, and filtered so that each frequency band contains equal energy. i.e. under subsequent analysis the spectrum display of pink noise will appear 'flat'.

#### INPUT

This section is to provide the analyser with easily managed, coherent analogue signals from sources of different levels and impedances. 'Microphone' or 'line' input can be selected; amplified or attenuated, and 'A' weighted, as required.

#### FILTERS

Thirty 1/3 octave frequency bands as represented on the display.

#### RECTIFIERS

Each of the filter outputs are fed into separate rectifiers. These produce D.C. voltage outputs, the level of which depend on the analogue input from the corresponding filter.

NOTE: A separate broad-band filter is employed to provide the overall level signal. This feeds two further rectifiers (one peak-reading - the other averaging). This is further explained in the Overall Level Technical Description.

At the outputs of the rectifier section, thirty-two separate varying D.C. voltages represent the changing energy levels of the filtered signal information.

#### MULTIPLEXER (MUX)

The thirty-two inputs are each sampled successively, in numerical order, and the samples fed through to the A/D converter. Each sample is 500 $\mu$ s long; the total cycle being approximately 15ms (a mark/space ratio of 1/32).

### A/D CONVERTER

The (logarithmic 32 X 1dB step) converter translates the D.C. level provided by the 'mux' into a digital 'word', which is fed onto the data-bus when commanded by the processor.

### PROCESSOR

The brain of the DN60 is the microprocessor. Supported by a permanent memory (ROM) containing the programme, it collects and manipulates information, with aid from a short-term memory (RAM). Incoming information is translated (decoded), into a form usable in the display section.

### SWITCHES

Whilst working in programme and digital signal information, the processor also monitors and services control requests from the push switches (e.g. change from 1dB resolution to 2dB etc.), and selects relevant status LEDs to be lit.

### DISPLAYS

Decoding data sent from the processor via the data-bus, the two display drive sections (X plane and Y plane) provide a multiplexed display pattern to the display LED matrix. Similar to the 'mux' described earlier, the 'X plane' selects each of the (frequency) columns successively and the 'Y plane' switches on the number of LED (energy level) rows required in each column (for the correct display pattern).

### NOISE SOURCE

To provide the reference signal required, Pseudo-random 'white noise' is generated digitally, and fed via a low-pass filter to a gateable op-amp which drives the pink noise output.

### MOTHER BOARD

Used to interconnect the processor with all other areas of the unit as required.

### POWER SUPPLY

The power supply is not included on the block diagram. It uses split primary & secondary windings. The transformer has three secondary windings, each driving their own full wave bridge rectifier, smoothing capacitor and integrated circuit positive regulator. So producing +8V, -8V and 5V rails. Also from the +8V taps, a +14V unregulated phantom power line is produced.

The two primary windings are connected in series or parallel by SW2 to give 220 or 110 volt nominal operation.

### ICI CARD

Not included in the block diagram, the ICI Card is used to interface the DN60 with external equipment.

## TECHNICAL DESCRIPTION

### INPUT (Circuit diagram sheet 1 Analogue Section)

The input section operates from two sources;

Line input is via a differential op-amp stage (U2A) which attenuates the signal by 18.5dB.

Mic input is via a similar configuration (U1), but with a variable gain of 10-20dB. This section also feeds the phantom power lines to the mic input socket.

Either line or mic source is selected by the first analogue gate (part of U3), the output of which is buffered and amplified by 3.5dB (U2D) before reaching the reference level section.

The reference level section employs a precision resistance ladder, situated on the 'A weighting' board (R8-R16), in conjunction with an op-amp (U2C) on the audio board. This configuration provides a dual function of attenuation/gain variable from -40dB to +30dB in 10dB steps.

The second analogue gate (part of U3) controls whether the signal is fed 'direct' (unweighted) or via the 'A weighting' filter (on a separate board) to:-

A 30dB amplifier section (U2B) before being fed (via a buffer on the mother board) into the filters.

### FILTERS AND RECTIFIERS

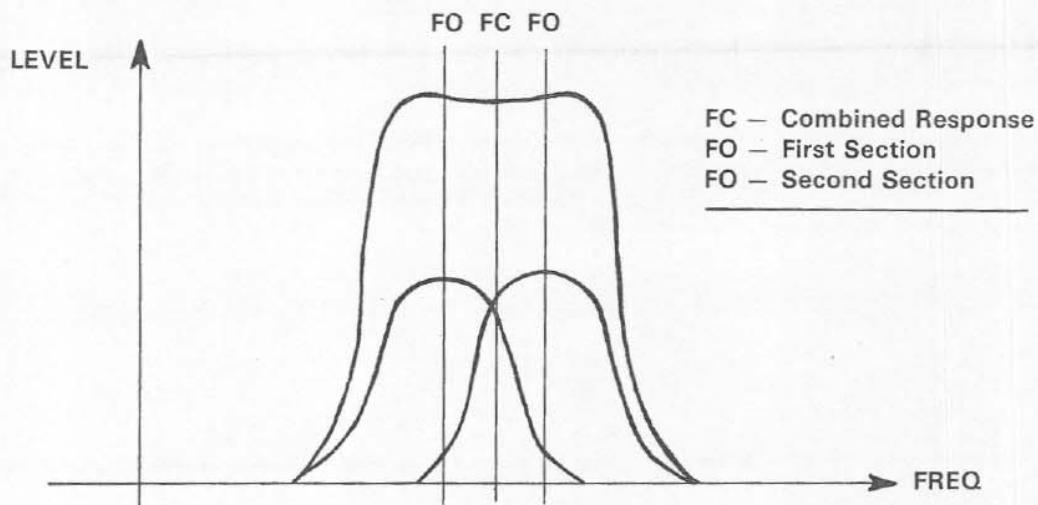

Filters and rectifiers are here dealt with together as they are situated on the same assemblies. (Circuit diagram sheet 6, Filter Section).

The combined filter/rectifier sections are located on 8 plug-in PCB assemblies mounted on the mother board. One of these (overall-level board) is described separately; the other seven are essentially alike, only frequency selective components and some rectifier time constants differ.

Each of these seven boards comprise, four filters of adjacent frequency bands (i.e. 25-50Hz on one board), and four corresponding rectifiers.

To achieve the required filter shapes, two band-pass filter sections are employed in series for each frequency band. The first section has its centre frequency slightly higher than the combined filter centre, and the second section slightly lower. The resulting frequency response has sharper slopes and a flatter top than provided by a single section.

(This configuration is referred to as a double pole-pair)

Each section has a gain of 9.5dB at FC, therefore the combined filter gain is 19dB at FC.

To compensate for component tolerances, each combined filter has a calibration pre-set which adjusts the combined filter sharpness (Q factor).

The filter output is fed into a precision rectifier which produces 900V D.C. output when the input level is -1dBm.

Note: To provide correct response times, lower frequency rectifiers have larger time constants and produce slightly higher output voltages.

#### OVERALL LEVEL (Circuit diagram sheet 6 Filter Section)

This board comprises two filters with corresponding rectifiers which are as those previously described, and the 'overall level' filter and rectifiers.

In the overall section the input signal amplified by a calibrated gain stage of 10dB. The following two-pole high pass and low pass filters produce a band-pass filter (approx. 13Hz-23Hz). At this stage the overall signal is still +10dB with respect to the input and feeds two rectifiers.

The peak reading rectifier produces approx. 900mV D.C. output for +10dB input.

The averaging section has slower responses and produces a lower output level. It is therefore followed by a gain stage to provide output level to the peak rectifier. This gain stage has provision for D.C. offset adjustment, allowing the peak and average outputs to be accurately balanced.

#### MULTIPLEXER (MUX) (Circuit diagram sheet 3 Mother Board)

To provide the serial form of information required by the converter from the thirty-two parallel rectifier lines, a 32 to 1 line multiplexer is employed.

U8 - U11 are 8/1 analogue switches (8 way; single pole), each servicing a block of 8 of the 32 input lines from the rectifiers.

From the tri-state latch (U7), three clock lines are used commonly by U8 - U11 to select 1 of 8 inputs. The 4 output lines (one from each chip) are connected in common to the A/D input.

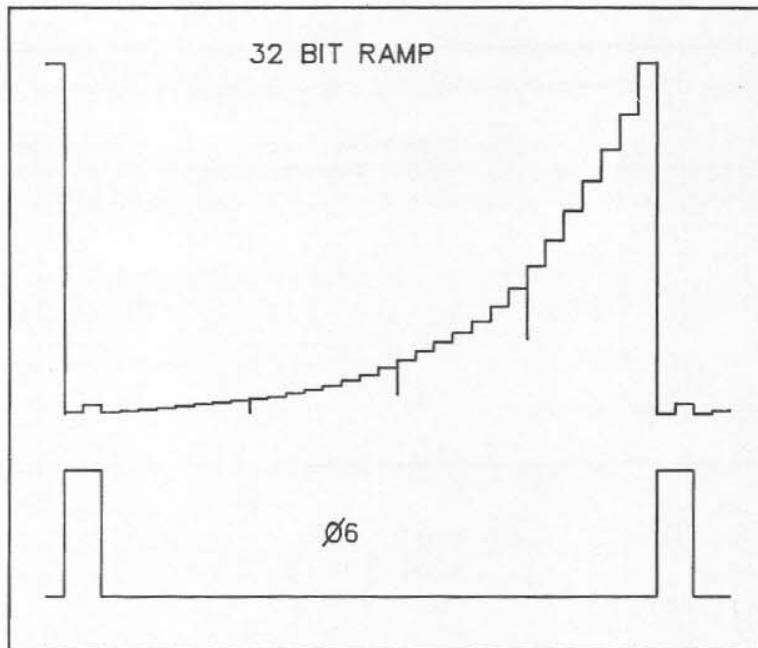

Two further clock lines from the latch are decoded by U5A+B and U6 to produce a 1 of 4 select. This enables only one of the switches to use the output line at any time, each being selected successively.

Thus, from data sent via the latch, a 5-32 line decode is performed to multiplex the 32 inputs onto a common output, in numerical order.

#### A/D CONVERTER (Circuit diagram sheet 5 convertor section)

The clock divider (U5) operates from  $\phi 2$  input received from the processor via a comparator (U1 C). Divided clock outputs from this are used to control 'on board' functions and  $\phi 6$  is also returned to the processor board to provide system synchronisation.

A resistance ladder (R11-R15) divides a precision D.C. voltage reference into  $4 \times 8$  dB steps. U3 is used as a 4 way switch, which controlled by two clock lines, produces an output stepping up from -24dB to 0dB (with respect to the reference) U4, controlled by a further 3 clock lines, uses a second resistance ladder (R16-R23) to further divide the stepped output of U3 into 1dB steps. Thus, as the clock count progresses the output from U4 appears as a logarithmic step ramp ( $32 \times 1$  dB steps).

The analogue input voltage is amplified by a calibrated gain stage (U2A), before it is compared with the ramp (by U1B).

When (if) the ramp voltage steps above the compared input level, a latch (U7) is enabled via U6 (D type latch). the status of the 5 clock lines controlling the ramp is latched (by U7) and provides a 5 bit word which represents the input level converted.

If the input level is more than 1dB below the lowest step of the resistance ladder (31dB below the reference voltage), the output latch is enabled as normal and the output of comparator (U1A) will be latched as bit 7 (D6) of the data word, to indicate an 'under range' input condition.

If the input is greater than the D.C. reference clearly the ramp cannot step above it (i.e. U1B will not latch U6), and a sixth clock line then enables the output

U6), and a sixth clock line then enables the output latch as bit 8 (D7) of the data word, indicating an 'over range' input condition.  
Note: bit 6 (D5) is not used in the conversion process.

So the converter translates the input level into a 7 bit word, 5 bits give a level in the range 0dB - 31dB in 1dB steps, which is only valid if the remaining 2 bits do not indicate an out of range reading.

Once the conversion cycle is complete Ø6 (M.S.B. of clock divider U5) signals the microprocessor to start the cycle again. The microprocessor derived S8, then resets the clock divider and latches via a comparator (U1D). This initiates the next conversion cycle.

U8 and U9 serve to i) load the input thus speeding up the release times of the rectifiers (using R35), and ii) modify the gain of U2A (using R24-R28) to compensate for the loading.

Note:- This section is only operative when the RT60 option is used. It has no effect otherwise.

#### PROCESSOR BOARD (Circuit diagram sheet 4 micro section)

The microprocessor (U1) executes programme functions with consideration to interrupt requests and signal data.

The external socket (EXT SKT) allows interface for external units to assume control of the DN60, via the ICI Card. This is relevant only when using optional add-on units.

The processor is dependent for control on 2 buses.

- i) A 16-bit 'Address' bus is used, directly to find required memory addresses in the ROM and RAM sections, and indirectly to 'select' other sections inside the DN60. Basically, this bus provides 'send' or 'receive' commands to the section with which the processor requires contact.
- ii) An 8-bit bi-directional 'data' bus which carries information to/from the processor and the required section (selected by the address bus). Data will consist of memory information, signal information etc.

Data travels to/from the processor and several other sections. Because the bus is common (shared), it is necessary to control which section the processor is able to communicate with, whilst also inhibiting all other sections from using the bus at that time. (Effectively, 8-bit words are multiplexed onto bus in series).

To do this, data is sent to, and received from, the required section via 8-bit, tri-state latches, enabled to use the bus by the corresponding command (decoded from the address bus).

- \* Data lines to the 'X plane' board do not require this latch, and will be explained later.

U2 is a 2K X 8-bit ROM (read only memory), containing the programme used by the processor, and is addressed by bits A0-A10.

- \*  $1K = 1024$  or  $2^{10}$ . This is the number of different address locations available to store data.  $2K = 2^{11}$ , therefore, 11 address lines are required to find all locations.

U3 is a spare socket connected as U2 to allow use of extra programme memory, should it ever be required.

U4 and U5 are 1K X 4-bit RAM (random access memory), used as short term memory stores by the processor. Being 4-bits 'wide', two are used in parallel to service the 8-bit data bus. They are addressed by A0-A9.

Because the micro requires different amounts of time to process the various programme routines, U6 is used to 'hold off' the processor until the outside sections are 'ready' to receive further instructions. The input line  $\bar{Q}6$  from the A/D board is used to activate this function, and this provides synchronisation for the entire unit ( $\bar{Q}6$  being derived from  $\bar{Q}2$ , which is itself produced by the processor).

U7 is a 3-8 line decoder using bits A13-A15. The resulting 8 lines are used to enable each section of the processor board (ROM, RAM, External Socket etc), to receive the address bus information only when required.

From bits A5-A9, U8 and U9 perform a 5-16 line decode function. Thirteen of these output lines provide the 'select' lines (used to enable the tri-state latches etc.), two lines operate via the External Socket and

etc.), two lines operate via the External Socket and one resets U6 (after each 500uS cycle).

The cycle speed at which the processor runs is controlled by U10A, C1 and R5, which produce the master clock.

#### SWITCHES/STATUS LEDS (Circuit diagram sheet 1 Analogue Section)

The switch board itself comprises of the 8 push switches and related status LEDs. It is serviced by 3 tri-state latches which are situated on the analogue input board. These latches are connected to the data bus controlled by select lines 1-3.

U6 (audio board) services the 8 switches, sending switch status information (if any switch is being pressed), to the processor when commanded.

U5 services 8 status LED lines (although these control 9 LEDs). It receives commands via the data bus regarding which LEDs to illuminate (dependent on which switch status).

U4 similarly services the remaining 6 status LED lines (controlling 8 LEDs).

The two remaining lines of U4 are used to control the Cmos analogue gates (discussed earlier), employed in the analogue input section.

#### DISPLAY (Circuit diagram sheet 2 display Section)

##### **Matrix**

The display LED matrix is serviced by two boards (X and Y plane), which produce a display in the following manner. The X plane drives the display columns (31 lines representing the 1/3 octave frequency bands), and the Y plane provides the energy level information (driving 16 rows). The X plane is scanned, each column being on for 500uS, during which time the relevant Y plane rows are switched on also.

Thus the total display is built up one column at a time and refreshed at a rate of approximately 70Hz. The eye therefore, only detects a continual dynamic display.

##### **X Plane**

U1 and U10 are 4-16 line latched decoders operating commonly from data bits 0-3. Each selects 1 of 16 output lines on in succession. Both chips are selected

together, but are enabled alternately by LD4 and LD4 which are derived from data bit D4 via a latch (U13 on the mother board). Thus, each of the 32 output lines are selected successively.

Each line, when selected, turns on a corresponding power transistor (combined in 8-quad chips U2-U9), providing a current sink for the LED column selected.

### **Y Plane**

U2 and U3 are tri-state latches which receive data from the bus when selected (separately). When enabled (by U5), the 16 output lines switch on corresponding power transistors (combined in 2 Octal packages U1 and U4). When on these source current into the relevant LED rows. (Each transistor drives a separate row).

U5 is a dual multi-vibrator, section 'A' operating as a display 'failsafe' via 'B', which controls intensity.

Triggered by S6, 'A' in turn triggers 'B'. VR34 sets the output pulse width from 'B' (which enables U2 and U3), thereby governing the mark/space ratio of display illumination and so controls intensity.

If the processor is 'crashed', S6 will stop; 'A' will not trigger 'B'. As U2 and U3 are not enabled, no display will appear.

### **NOISE SOURCE (Circuit diagram sheet 3 Mother Board)**

U1A, U2 and U3 form a psuedo-random digital noise source. At switch-on logic '1' followed by '0' is fed from C9 via D2 to the shift registers (U2 and U3). U1B, C, D, forms a clock which shifts these digits through the registers. By tapping information from the register at various points and recycling, a random process is formed. Once this process has been started D2 ensures that C9 has no further effect.

At U3 pin 10 random white noise appears. The succeeding 3dB/octave low pass filter, flattens the response to produce pink noise, which is essentially flat to 20kHz.

The 'signal' is amplified around a gateable op-amp (U4) and connected to the output socket. VR1 provides a fine gain control on later models.

U4 is gated on/off by two select lines. Using U5C and D as a latch, and Q1 and Q2 to convert 5V to -8V (required to gate U4). Noise is switchable, via processor control by the RT60 option.

MOTHER BOARD (Circuit diagram sheet 3 Mother Board)

The Mother Board provides the foundation of the DN60, carrying the bus systems, power rails etc., to all relevant sections. Whilst also housing the filters, A/D and processor boards on a plug-in system.

This board includes the line buffer, U12 (see 'input'), and a data latch (see 'X plane' drive) as well as a noise generator and multiplexer sections.

INTERFACE (Circuit diagram sheet 7 PSU/Interface Section)

The ICI card option provides interface capability with external devices. It is linked via the processor board EXT SKT to the data bus, address bus, decoded address (select) lines and other processor control functions.

U1 is a 2K X 8-bit ROM containing additional programme information.

U2 is not normally used but can contain further programme information.

U3 and U4 are 1K X 4-bit RAM used in parallel for short term storage of 8-bit data information.

U6 is a parallel interface port, providing interface capability with external units via the external socket (SKT 3).

The RT60 socket (SKT 2) is for use with the RT60 only and connects the data bus and addressing information to the RT60.

## PRELIMINARY INSPECTION

Before despatch of a unit to a customer, or upon return for repair/service, it is advisable to carry out the following preliminary inspection (and accordingly rectify any obvious fault). Carefully open the unit and check there are no:-

- loose or broken wires or joint
- boards broken or adrift inside the unit, or loose on its connectors
- burnt, broken or missing components
- loose screws or nuts
- and that the correct mains voltage is selected.

Assuming no problems arise thus far, apply power to the unit and check its operation.

Check:- 'warm up' routine, pink noise source, line and mic inputs. Ensure all LEDs illuminate and switches operate correctly.

## TYPICAL FAULTS

The DN60 is a complex instrument, and as such a comprehensive fault diagnosis would be extremely large and complicated; and mostly redundant! Some typical symptoms can be briefly outlined, and simple checks should quickly identify most faults. Complicated problems are quite unlikely to occur and would require sophisticated test equipment to be rectified.

### IN GENERAL

If a fault appears:-

- 1) Switch the unit off, wait a few seconds and then switch it on again.
  - a) If the unit now operates correctly it may be mains borne interference provoked a temporary processor error.
  - b) If the fault persists, carry out a visual inspection before using the test equipment.
- 2) Check the power supply before looking further for faults.
- 3) Having isolated the area or assembly at fault, before referring to circuit diagrams, visually check again for obvious causes (broken or burnt components, stray wires, loose connectors etc).

### POWER SUPPLY

Many problems can be identified before opening the unit, by observing carefully the 'warm up' procedure and noting what follows it.

- 1) Positive 8V rail - failure identified by:-

No display, 'OK' not shown, status LED on permanently. (3 stay off).

Check F2 is intact. Check 8V is present at SKT1 pin 3 and SKT2 pin 4.

- 2) Negative 8V rail - failure is indicated by:-

Normal warm up procedure followed by full display (overload), status LEDs as normal.

Check F3 is intact. Check -8V is present at SKT1 pin 1 and SKT2 pin 5.

3) 5V rail - failure may be indicated by:-

No display at all, no status LEDs.

Check power card is connected. Check F4 is intact. Check 5V present at SKT1 pin 6 and SKT2 pin 1. Remove power and check F1.

Further symptoms may be caused by supply failure to only one section, it is always wise to check.

Most faults can be recognised by watching the display (and status LEDs during and after 'warm up'. These may be interpreted as being in the display section itself.

1) Single LED failure - the indication is self explanatory.

2) Row of LEDs fail -

- a) Loose connectors
- b) Fault in corresponding section of the 'Y' plane drive board.

3) Column of LEDs fail -

- a) Loose connectors
- b) Fault on 'X' plane drive board
- c) Fault on corresponding filter(s)
- d) Fault in corresponding mux channel(s)

4) Sections (regular columns) fail -

- a) Faults as listed under 3
- b) Data line(s) missing
- c) Fault in 'X' plane decode.

Part '3' here can be used to illustrate how further resolution of the problem is possible.

The failure of a column indicates one of three possible faults (excluding loose connectors), which can be isolated by two further checks.

- i) During start-up, if the column in question lights, then clearly the fault is in the corresponding filter (e.g. 100Hz) or multiplexer channel.
- ii) Swapping the suspect filter board for another (say 6K3Hz), will indicate whether the problem is in the 100Hz filter or the 100Hz mux channel.

As all possible faults cannot be covered here, the intention is to illustrate that applying common sense should dictate the direction for fault finding, with reference to circuits, overlays, descriptions and line-up information.

## I.C.I. RETROFIT KIT

<u>ITEM</u>	<u>DESCRIPTION</u>	<u>PART</u>
1.	I.C. U3 Microprocessor card	Prom 024 (LGB 1 & RT60)
2.	4 X Pillars	23mm Type B
3.	I.C.I. card fully loaded & tested (programme 023)	

### DN60 PROGRAMMES REQUIRED FOR RT60 OPTION/LGB 1 OPTION

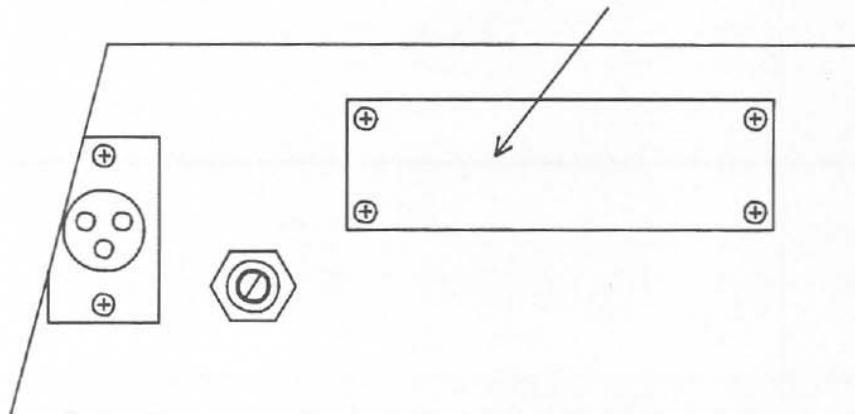

Processor Board - U2 is T.Bug 022, U3 is T.Bug 024

I.C.I. Card - U1 is T.Bug 023

### I.C.I. FITTING

1. Remove DN60 covers, (8 screws).
2. Remove blanking plate. (4 screws) sketch fig. 2 from rear of DN60.
3. Insert T.Bug 024 (24 pin I/C) into spare 24 pin socket marked 'U3' on microprocessor board. see fig. 3. Ensure correct orientation of pin 1 (see fig. 4), (this may already be present on later units).
4. Remove 4 nuts and washers which secure microprocessor board (fig. 3), and replace with pillars provided (Do not discard nuts and washers).
5. Carefully plug ribbon connector into 40 pin socket on microprocessor board marked 'EXT SKT' (see fig. 3).
6. Place ICI card on pillars so that RT60 and LGB connectors are accessible through the rear panel, and secure with the 4 nuts and washers.

REMOVE BLANKING PLATE

REAR VIEW OF DN60

Figure 2.

## DN60 MICROPHONE CALIBRATION PROCEDURE

Equipment required: B & K 4230 calibrator with 1/2" adapter.

- 1) Remove top cover from DN60 and set controls as follows:-

Response to 'l'; resolution to 1dB; peak (pk) reading; 'A weighting' off; reference level to 110 SPL.

- 2) Place calibrator over microphone and turn on, adjust mic level preset (shown on fig. 7b), so the 1kHz - 16dB LED is just turning off. Replace top cover.

## DN60 A/D AND FILTER CALIBRATION

(MkII filters, PCB Nos. 2568, 2555 and 2622)

### OVERALL CHECK LEVEL

Connect oscillator to line input of DN60 and switch DN60 to 'LINE'.

Set oscillator to 1kHz + 2Hz and arrange oscillator output level and DN60 'reference level' attenuator so that -10dBu is produced at Test point 1, TPI on the DN60 mother board.

Measure the overall level peak D.C. rectifier output @ pin 5 of molex connector SKT 13 (use high impedance probe - 1 meg or above. The output should be 900mv +30mv.

On later models VR4 is provided on O/L board and should be adjusted to give 900 mv +5mv.

Measure the overall level average D.C. rectifier output @ pin 6 of molex connector SKT 13, the output should be within 20mv of the reading taken at the peak DC rectifier output.

### A/D ADJUSTMENT

Arrange oscillator to give 1kHz @ +9dBu @ line input of DN60.

Set DN60 to 'Line', 'PK', Response '1' and resolution '1dB'.

Set DN60 reference level attenuator to +10dB.

Adjust A/D 'input level cal' VR9 so that the O/L - 1dB(+9) LED is at its turn on threshold (flickering on and off).

### FILTER ADJUSTMENT

Set oscillator to 25Hz @ -1dBu at line input of DN60.

Set DN60 to 'Line', 'PK', Response '1' and resolution '1dB'.

Set DN60 reference level attenuator to +10dB.

Adjust sharpness pre-set so that -11dB (-1) LED (25Hz column) is at its turn on threshold.

Adjust the input frequency slightly to find the filter peak and re-adjust the preset until turn on threshold is at filter peak. (This is not necessarily at the cf of the double pole pair filter network).

Repeat 3 for all other filters.

#### DC OFFSET

Set oscillator to 23kHz @ -27.5dBu.

Set DN60 to 'Line', 'PK', Response '1', 'peak hold' on and resolution '2dB'. Press 'Store'.

Sweep oscillator slowly down to 23Hz (must be at least 10 second sweep). All -38dB (-28) LED should be On.

Set oscillator to 23kHz @ -28.5dBu.

Sweep oscillator slowly down to 23Hz (as above). All -38dB (-28) LED should be OFF.

Note Individual filters with DC offset problems may be cured by replacing IC U3 or adjustment of R9, R19, R29, R39, by up to +100% - 50% of existing value. If large amounts of filters have offset problems the filters need not be adjusted. instead adjustment of A/D converter is recommended by selection of capacitor value across pin 1 and 2 of U2A on the A/D board, values from 8p2 - 120pf.

#### OVERALL LEVEL DC FINAL ADJUSTMENT

Set oscillator to give 1kHz @ -18dBu.

Set DN60 to 'Line', 'PK', Response '1' and resolution '2dB'.

Set reference level attenuator to +10dB.

Adjust oscillator input level by + 1/2dB to find the turn on threshold of the O/L -28dB(-18) LED. Adjust R39 if required to obtain threshold @ -18dBu - 1/2dB.

Reset oscillator to -18dB and switch DN60 to 'Average'.

Adjust VR3 to set the turn on threshold of the O/L -28dB (-18) LED at exactly -18dBu.

Measure frequency response @ Tp3 with reference to 1kHz

## NOTES ON FILTER IN DN60

### Filter Shapes to I.E.C. 225

$$\begin{aligned} f_m &= \text{mathematical centre frequency} \\ f_1 &= f_m / \sqrt[6]{2} \approx 0.891.f_m \\ f_2 &= f_m / \sqrt[6]{2} \approx 1.1225.f_m \end{aligned}$$

$f_m$  is calculated from  $f_1$  and  $f_2$  as follows:-

$$f_m = \sqrt{f_1 \cdot f_2}$$

$f_1$  and  $f_2$  are measured as follows:-

$$\text{level at } f_1 = \text{level at } f_2$$

These are approximately the 4dB down points.

$f_m$  is then calculated and checked for tolerance.  
 $f_m$  should be within +5% of stated frequency.

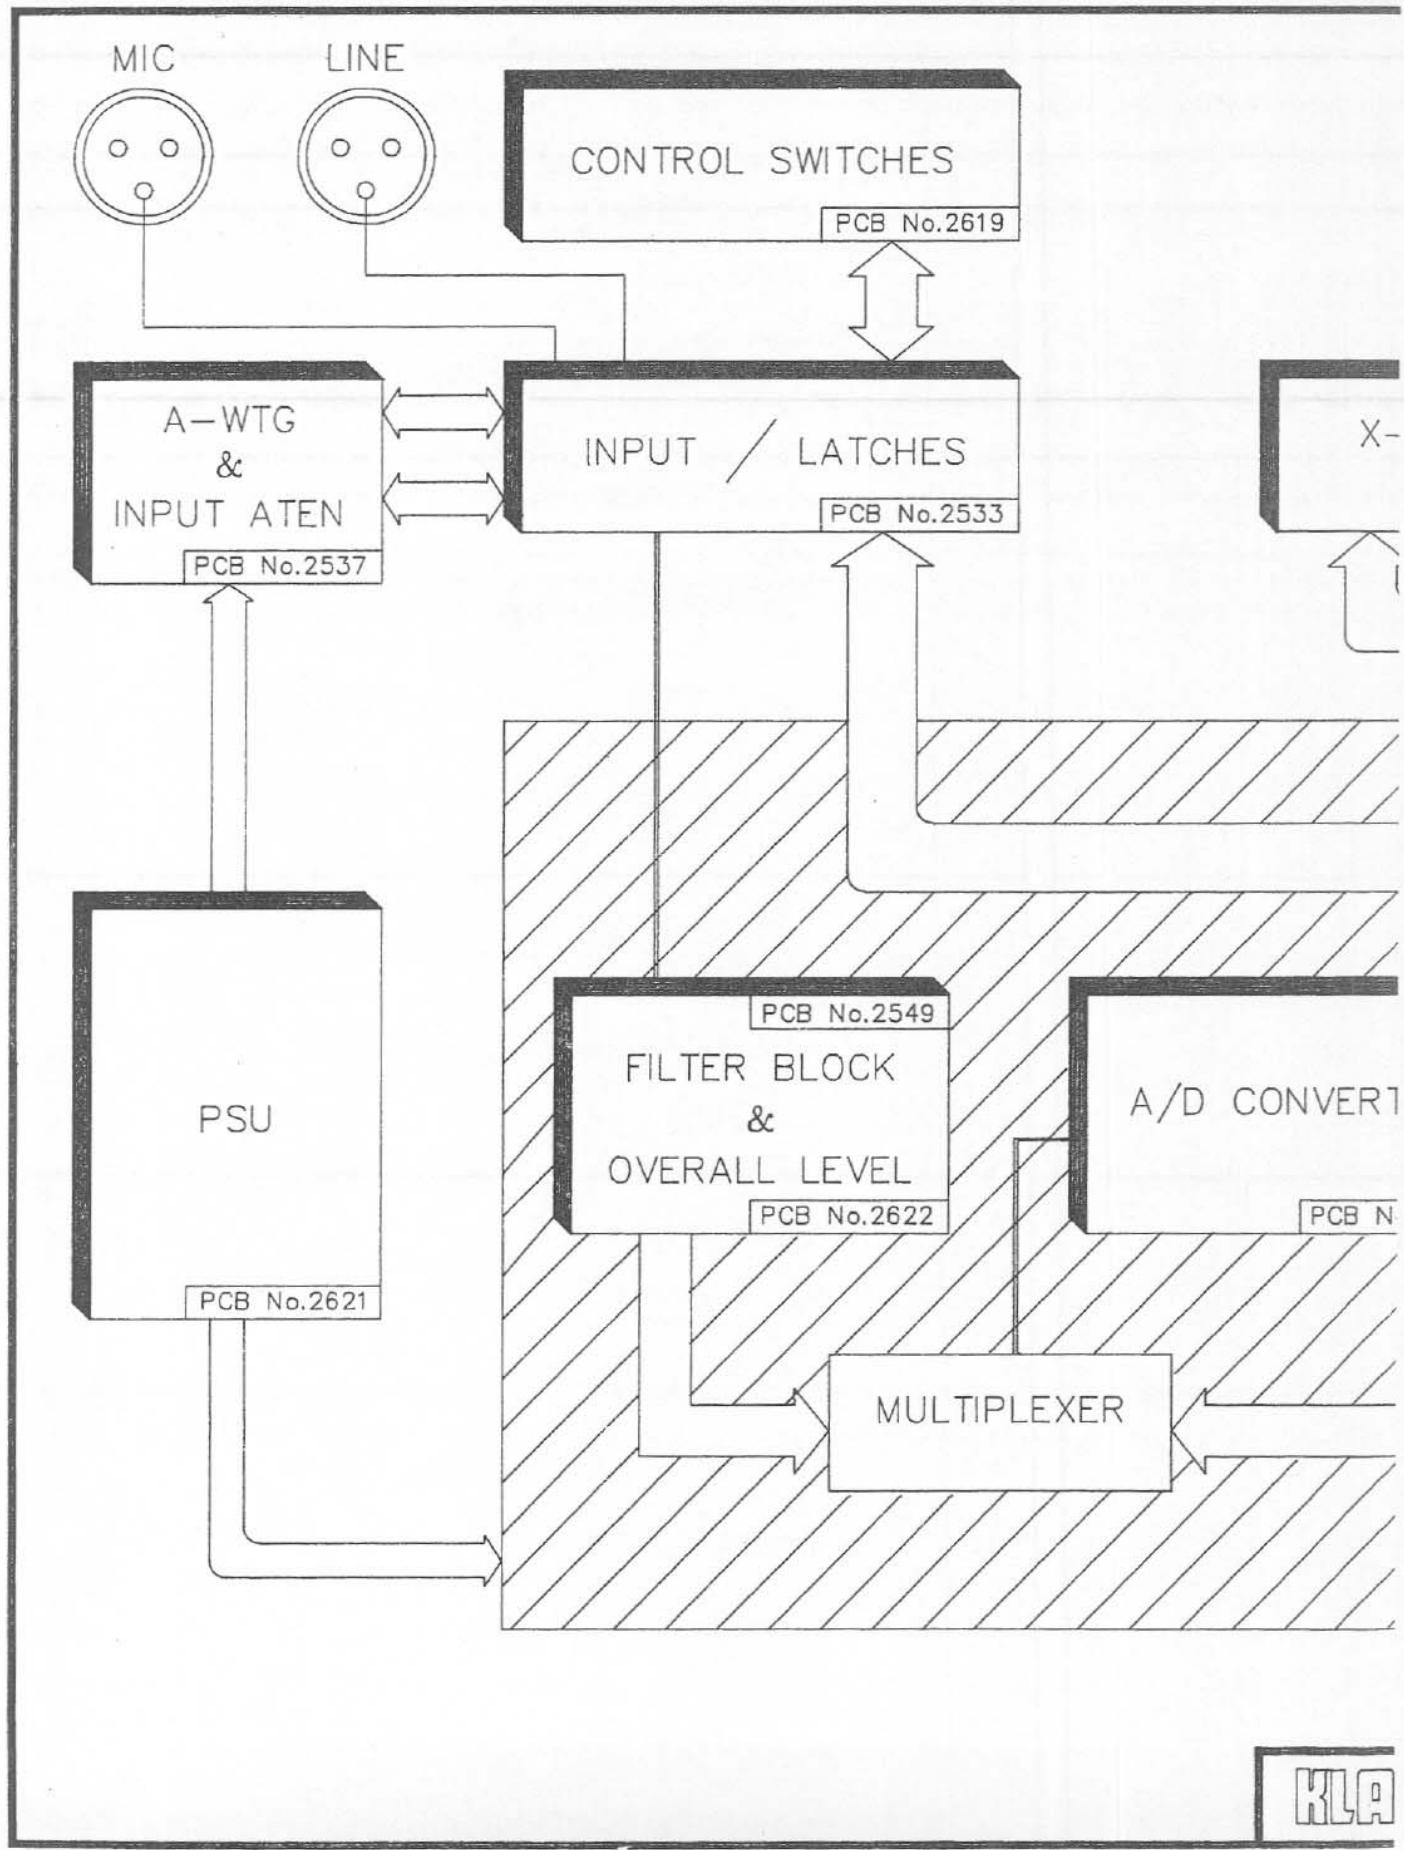

- Note
- 1) Centre frequency or effective bandwidth tolerance in I.E.C. 225 is +10%.
  - 2)  $f_m$  is not necessarily the maximum level, as ripple in the passband can be within + 0.5dB and -1.0dB.

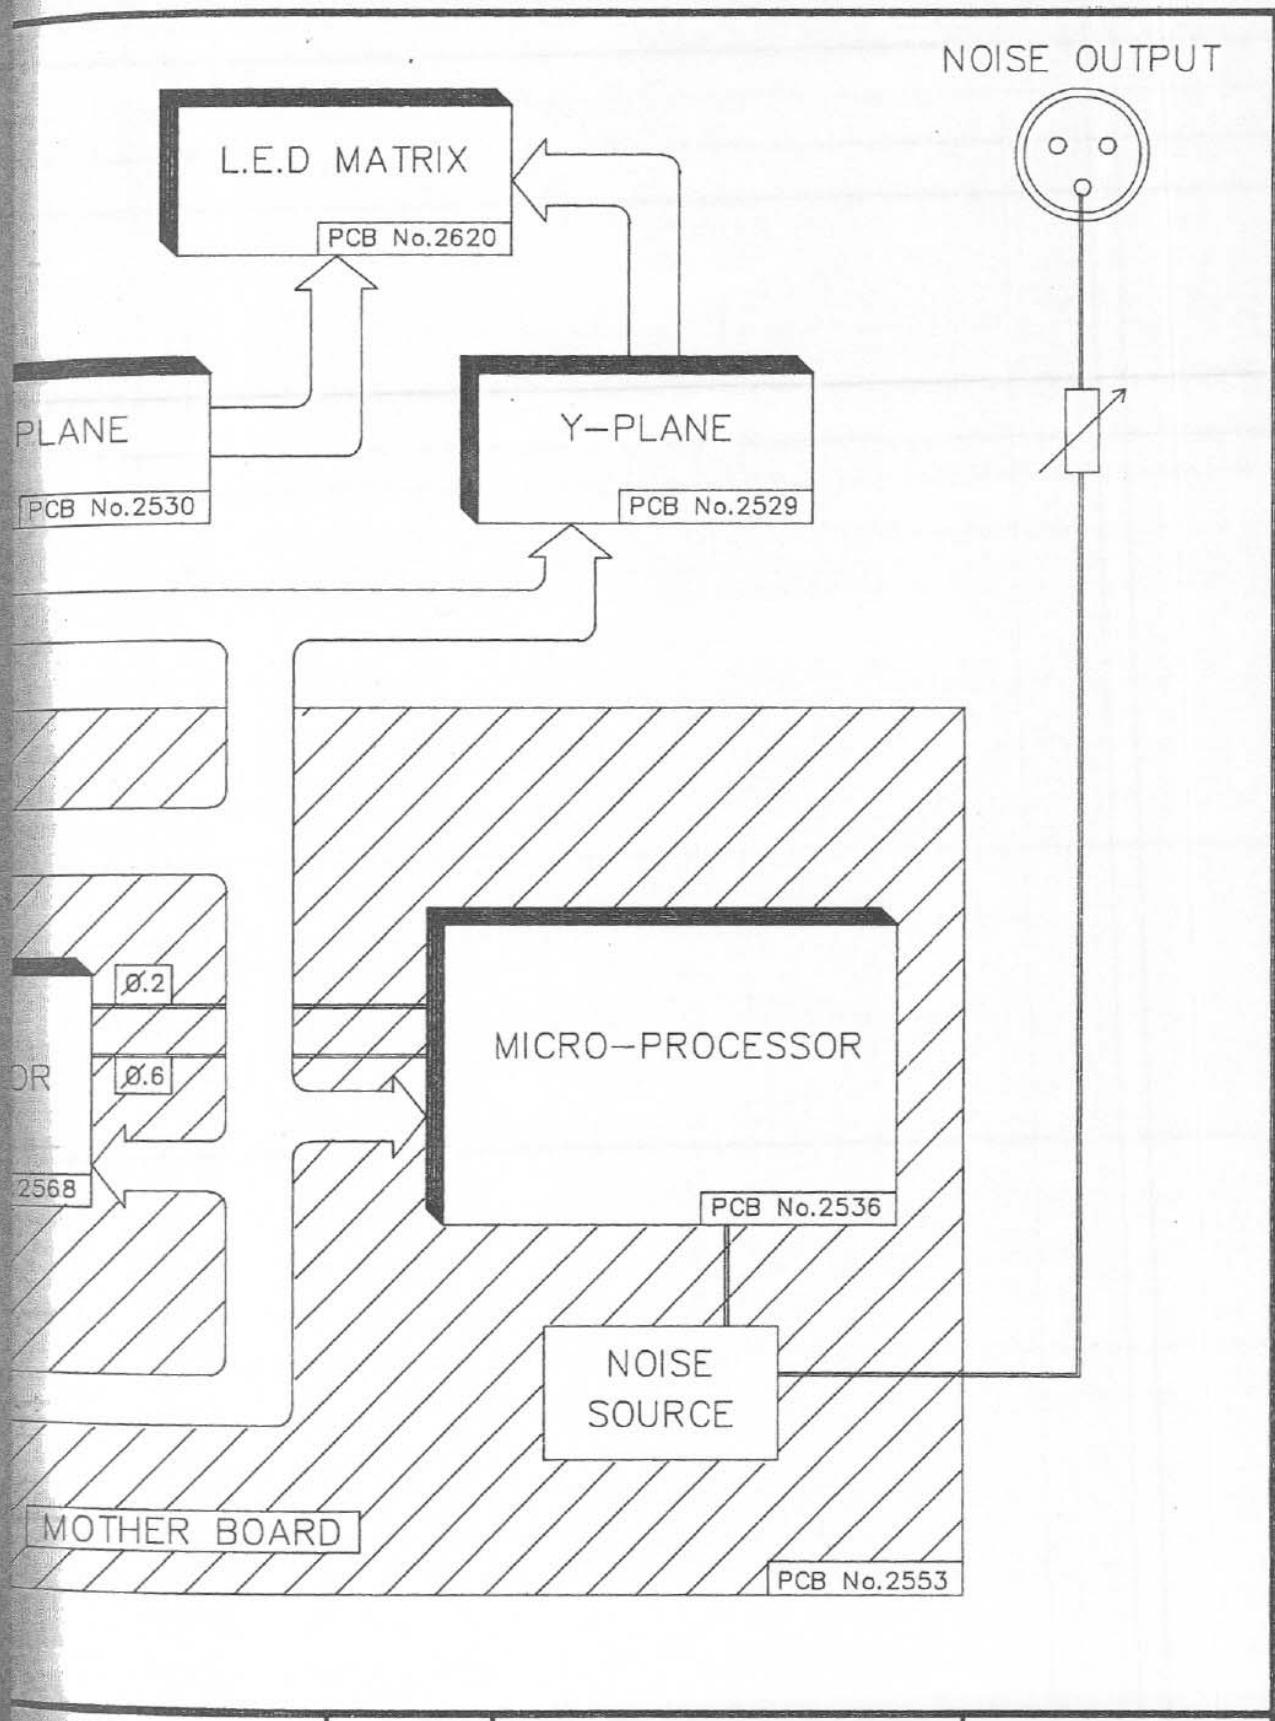

## DN60 FILTER/RECTIFIER TIME CONSTANTS

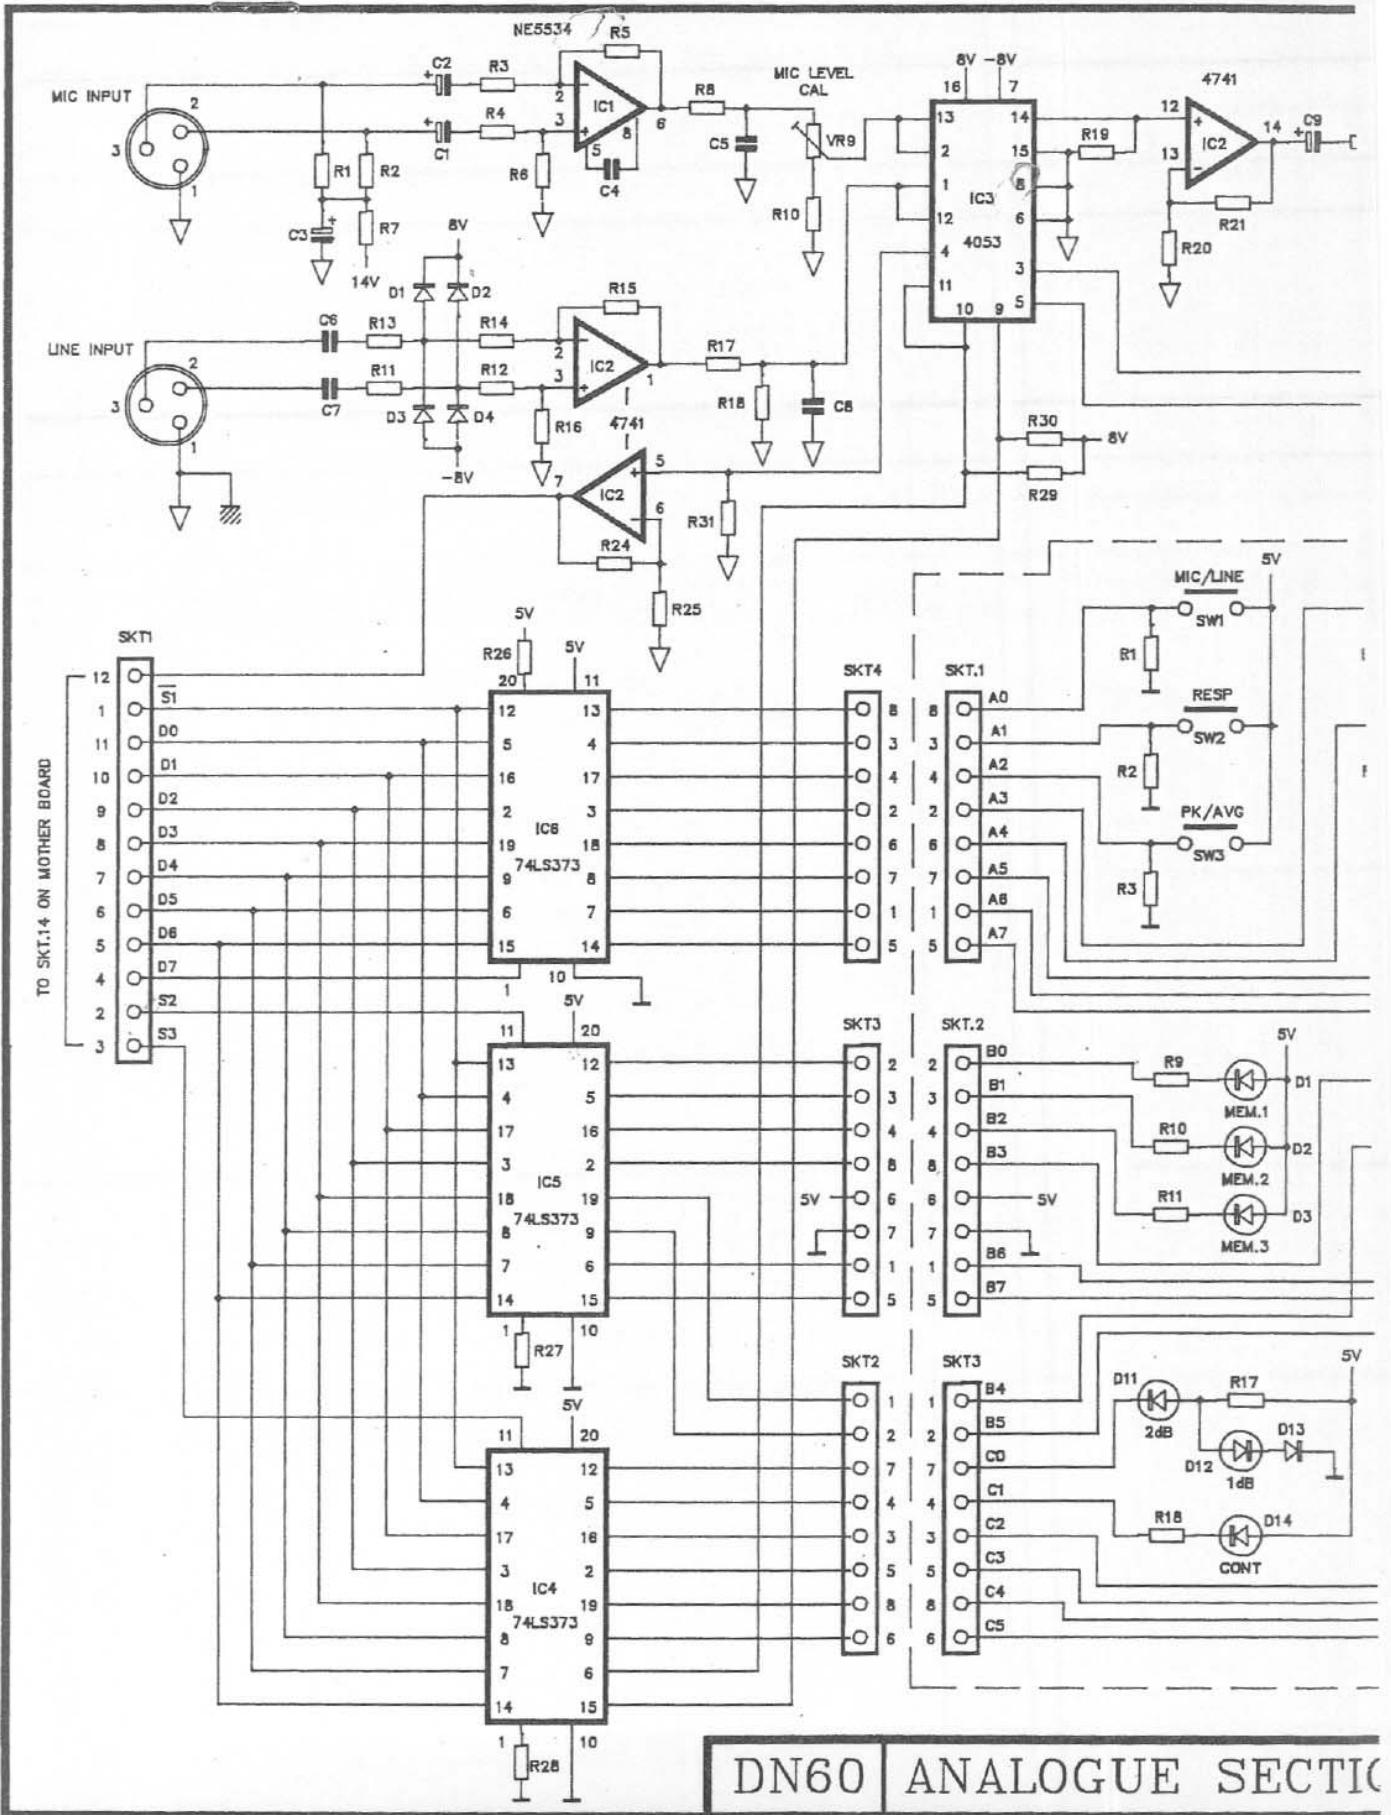

This table gives the attack and release times of the filter/rectifiers in the DN60, for all three positions of the response time switch, and both positions of the Peak/Average switch. The time constant is stated as the time taken for the column of LED's to reach 0.66 (-4dB approx) of its steady state value on attack and to fall to 0.33 (-9dB approx) of its value on release. In order to gain optimum performance in visual representation of the incoming signal, these times vary with frequency.

All times are in milliseconds and only approximate.

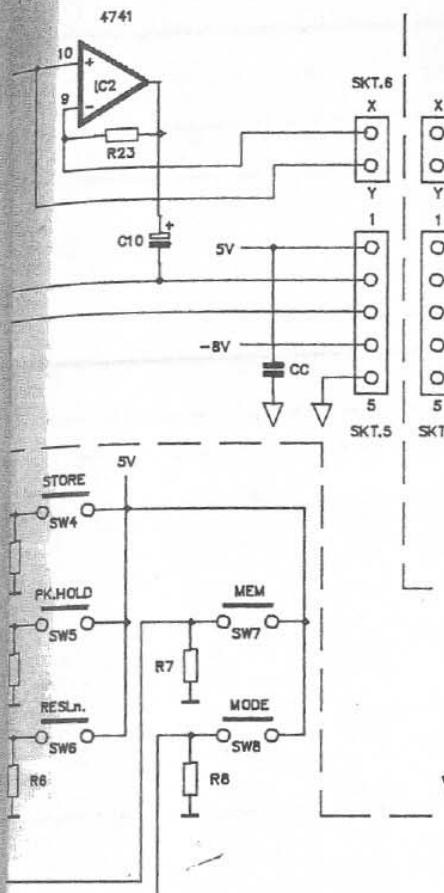

Frequency Column	RESPONSE		
	1 (Fast) Att/Rel	2 (Med) Att/Rel	3 (Slow) Att/Rel
Overall Level Ave.	300/350	400/550	1000/1800
Overall Level Peak	1/350	1/550	1/1800
25-40Hz Average	180/1000	250/1300	1000/3000
25-40Hz Peak	160/1000	160/1300	160/3000
50-100Hz Average	110/700	240/1000	1000/2500
50-100Hz Peak	80/700	80/1000	80/2500
125-200Hz Average	110/350	240/550	1000/1800
125-200Hz Peak	40/350	40/550	40/1800
250-20kHz Average	110/220	250/400	1000/1600

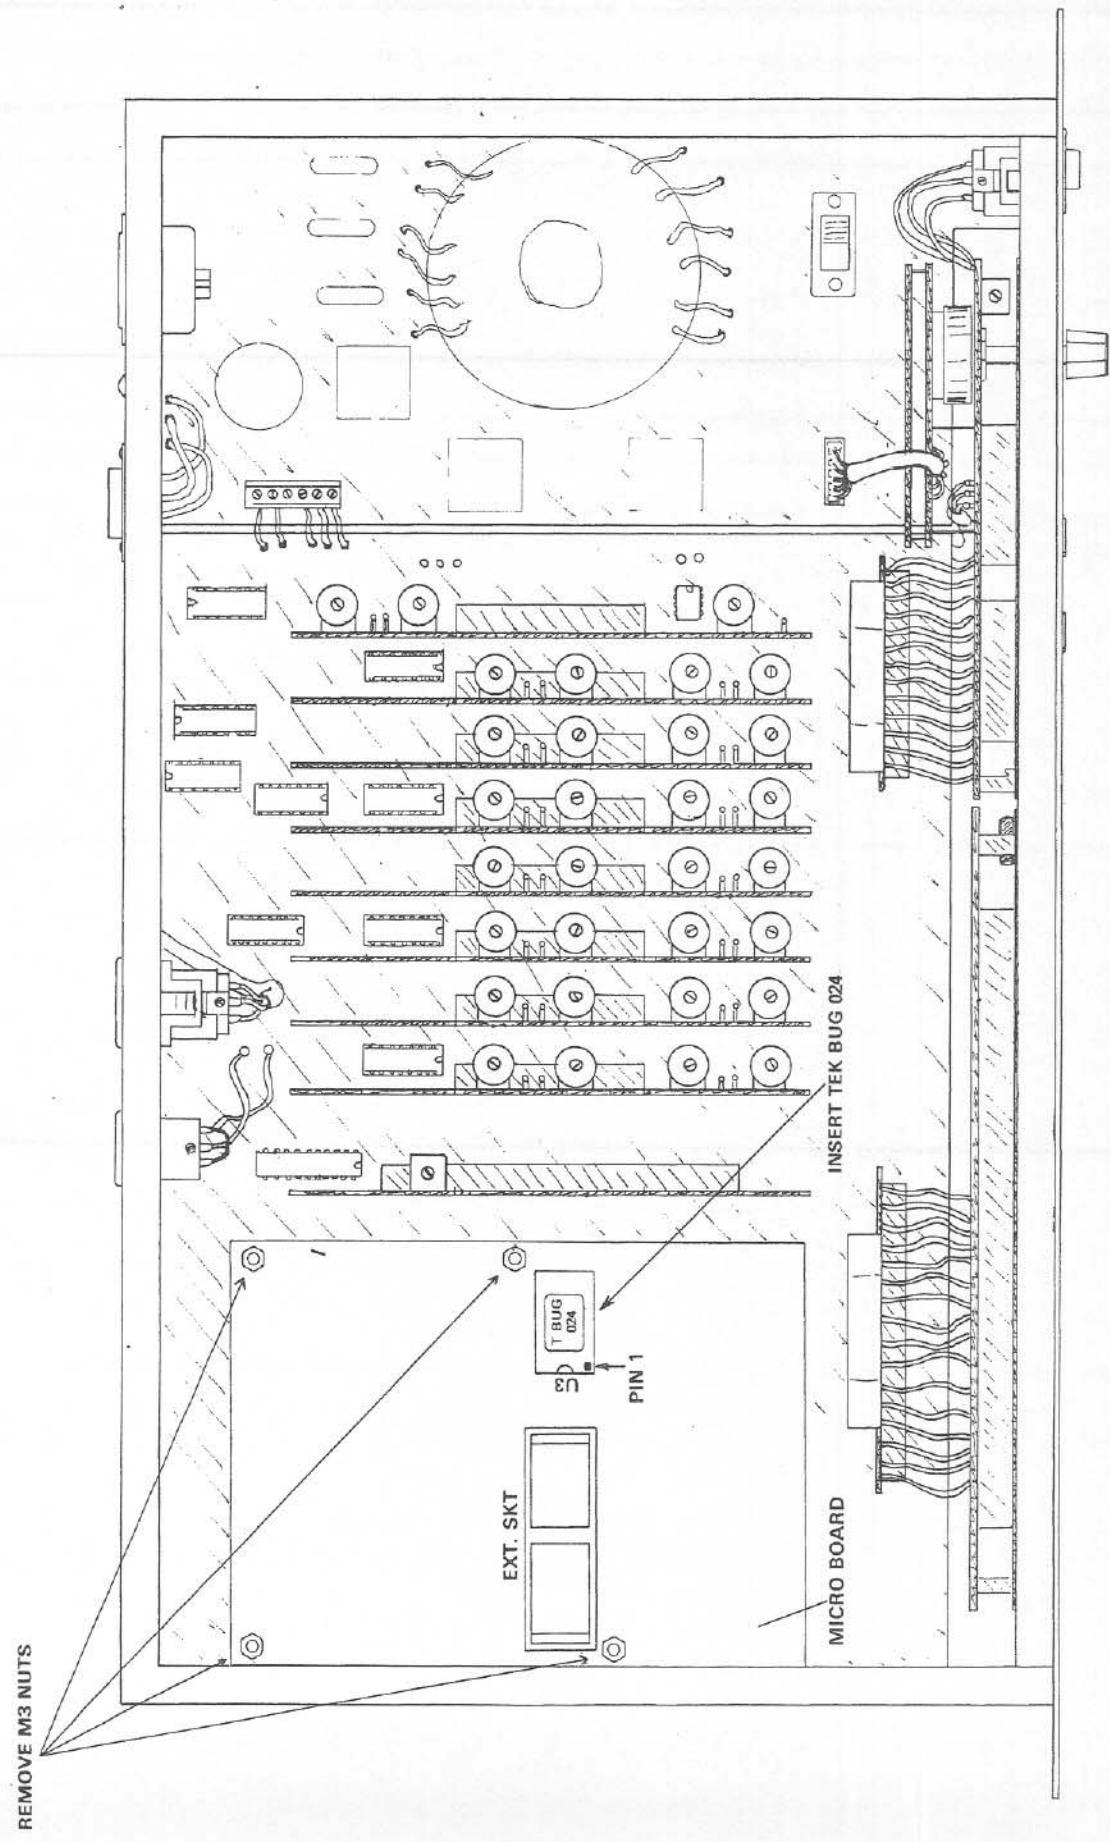

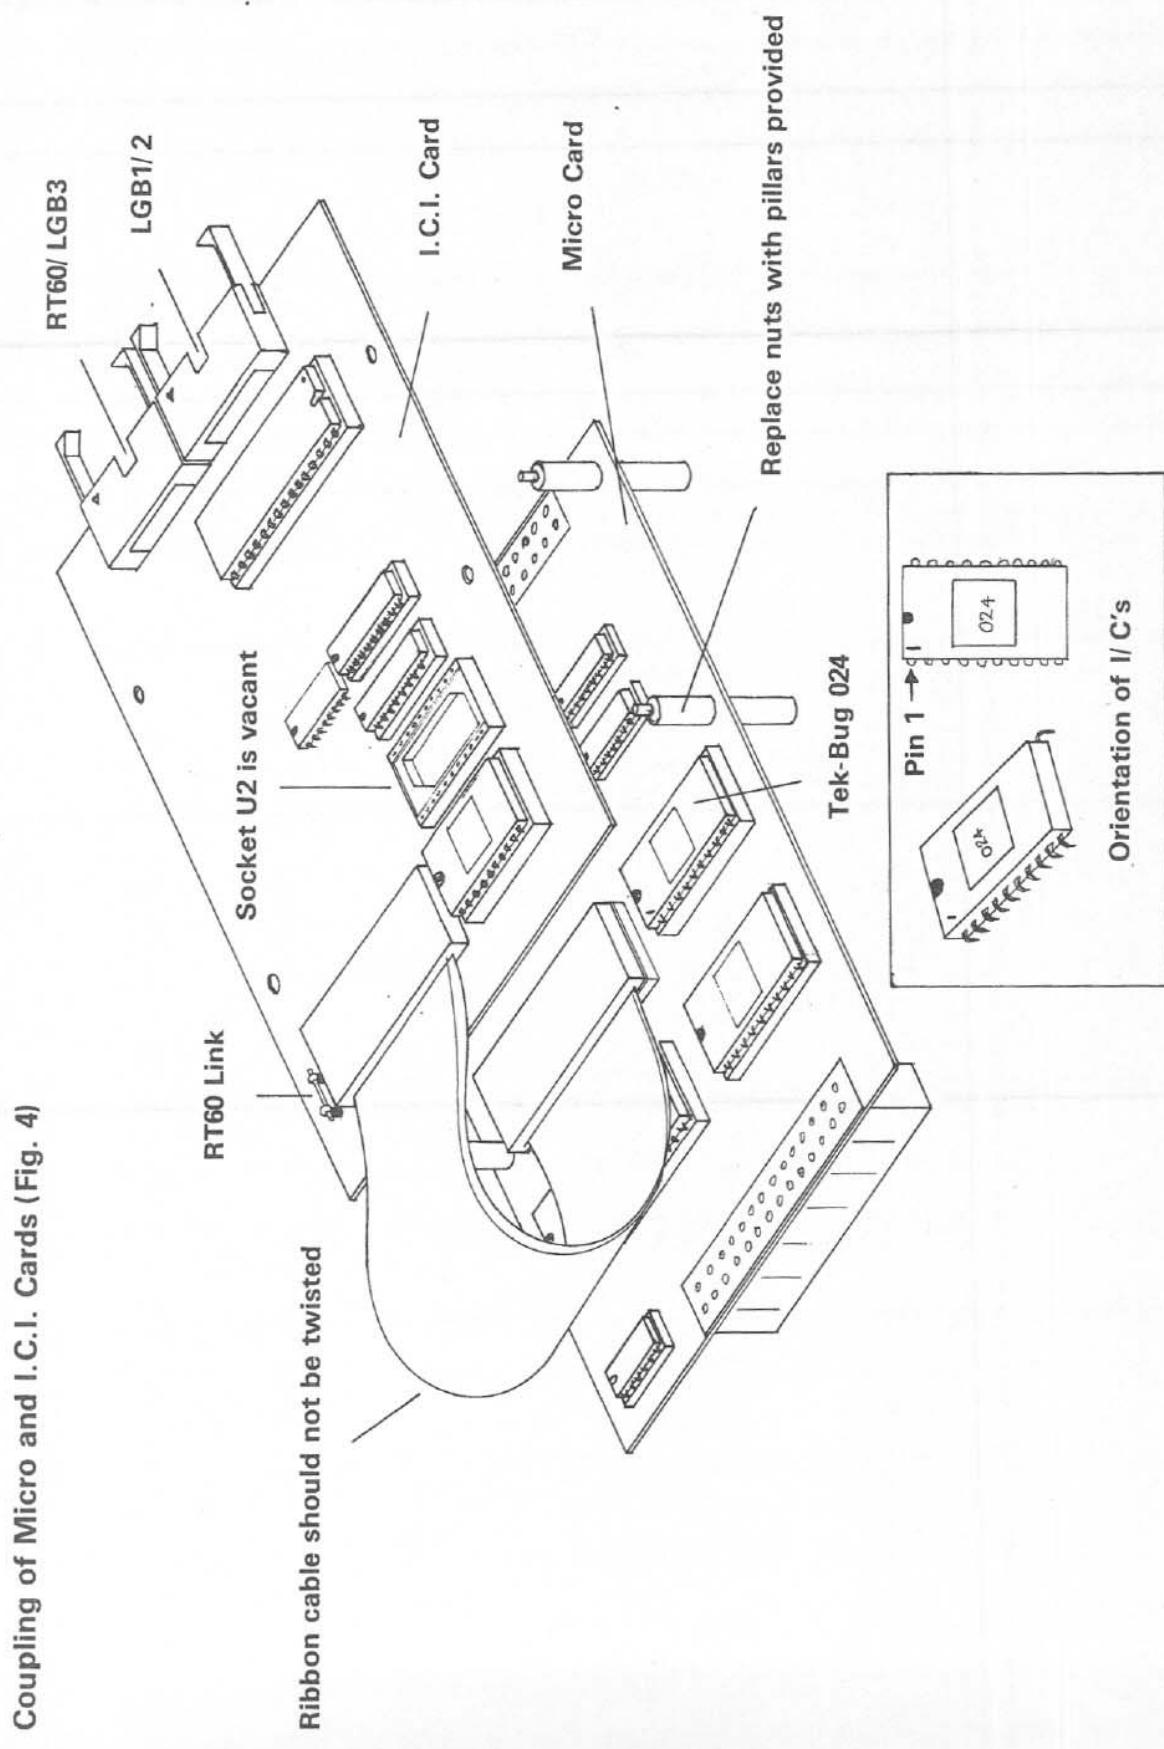

Figure 4

## DN60 INTERFACE

The Right Socket is only for connection to the RT - 60 All other external devices are connected via the Left socket (called the External socket).

The External socket continuously 'sends' a digital code corresponding to the DN60 display...

**NOTE.** This data is output only, there is no facility for data or control input to the DN60.

The LGB 1 contains all the circuitry to enable the display to be monitored on an Oscilloscope (or any X-Y) screen, or to be printed out on an X-Y recorder (plotter).

The enclosed timing diagram and connector details will be necessary if the user wishes to connect the DN60 to any other external device (e.g. Computer).

### DN60 External Socket Connections

<u>Pin No</u>	<u>Code Name</u>	<u>Description</u>
1	PB7	Not Used
2	PB6	Not Used
3	PB5	Strobe
4	PB4	Data 4
5	PB3	Data 3
6	PB2	Data 2
7	PB1	Data 1
8	PB0	Data 0
9	CB2	Trig.
10	PA0	No Connection
11	CA2	Not Used
12	CA1	Not Used
13	PA1	Connect to 0V.
14	CB1	Not Used
15	0V.	
16	+ 5V.	

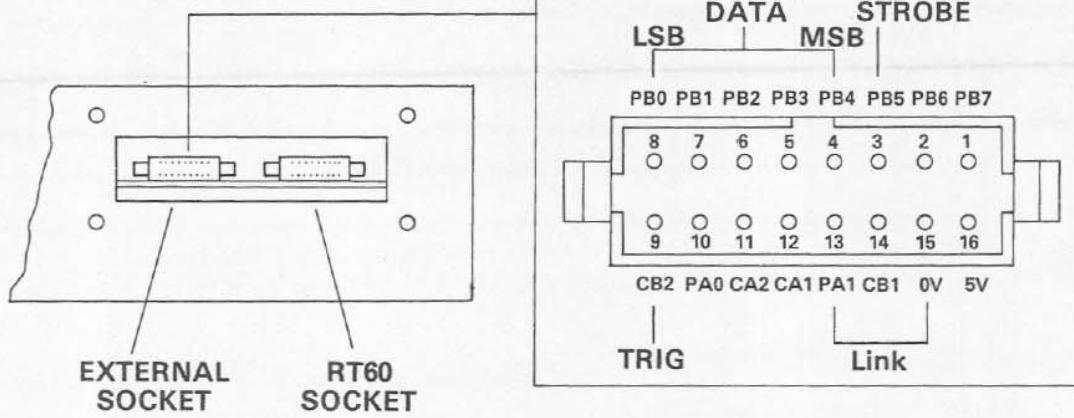

A five bit digital word of information is sent out on Data lines D0 through to D4, every 500 microseconds. This 5 bit word is the level of a single column on the DN60 display, represented as 32 x 1 dB steps.

00000 = less than -31 dB.                    11111 = 0 dB.

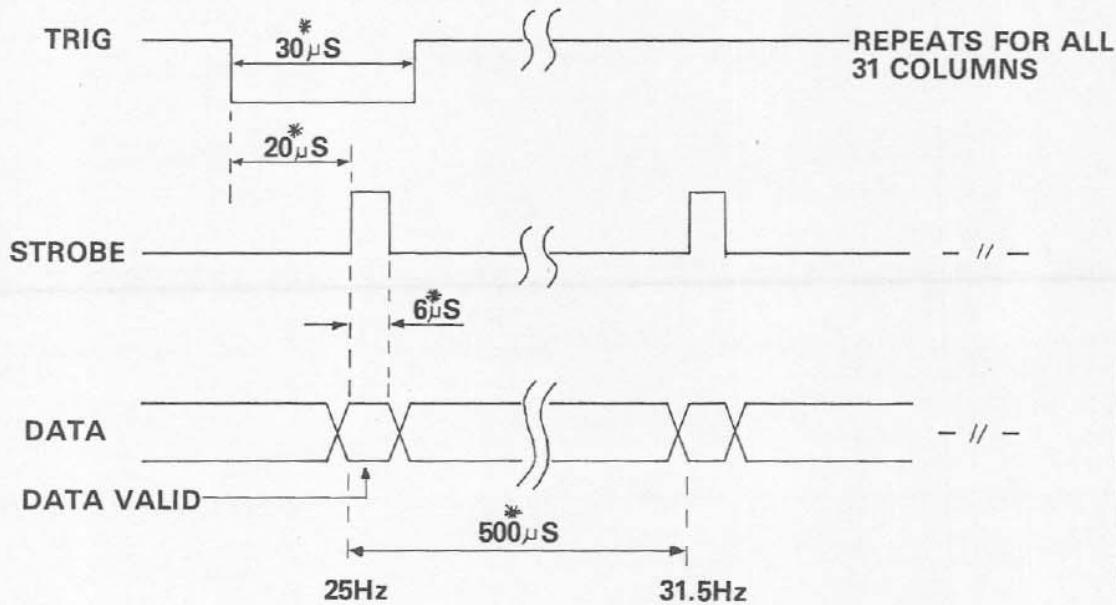

The sequence is started with a pulse on the Trig. line. This is followed by the 31 columns on the display, starting with 25Hz. and finishing with overall level.
