vs Time: +0.002% in 1 minute or less; 0.01% in 1 hour or less.  
vs Temperature: 0.05%/°C.  
vs Line: >0.001% for 10% change in line voltage.

FREQUENCY STABILITY:

FREQUENCY ACCURACY: +2% of setting calibrated at 3 dial settings (1, 3, 10).

FREQUENCY RANGE: 1Hz to 100Hz.  
FREQUENCY CONTROL: Five pushbuttons of decade multiplication with an infinite resolution single turn dial calibrated in Hz from 1 to 10 provides continuous frequency coverage. Also, a vernier covering +5% of the frequency setting is provided for intricate adjustments.

1.2 SPECIFICATIONS

The Model 4500 has been carefully inspected, tested and aged before shipment to insure that it is working properly. If the oscillator appears to have been damaged in shipment, inform the freight carrier of the damage and notify Krohn-Hite or its nearest sales office immediately.  
When combined with Krohn-Hite's Ultra-Low Distortion Analyzer 6800A/6900 Series, it provides a complete distortion measurement system.

Frequency tuning is provided by a 10:1 tuning dial and a 5 band decade multiplier.

Simultaneous INVERTED (180°) OUTPUT is provided for synchronizing a scope or as an auxiliary output. The output is fixed at 7 volts rms from a 600 ohm source impedance.  
The unit delivers up to 7 volts rms open circuit to MAIN and INVERTED OUTPUTS of 600 ohm impedance. A MAIN OUTPUT of 50 ohms impedance is also provided. A four position pushbutton ATTENUATOR calibrated in 20dB steps together with a 30dB vernier provides a total dynamic range of 90dB. Amplitude and frequency stability varies less than 0.001% with a 10% change in line voltage.

The 4500 produces a virtually "distortion free" (<0.001%) sine wave for measuring harmonic distortion in audio pre-amplifier and power amplifier circuits. It also generates square waves with aberrations of less than 5% peak to peak amplitude. The exceptionally flat response of the 4500 (+0.05dB) eliminates the need to constantly monitor voltage levels during amplifier response tests.

The Krohn-Hite Model 4500 is an ultra-low distortion, stable amplitude oscillator designed for test and measurement applications in the 1Hz to 100KHz frequency range.

1.1 INTRODUCTION

GENERAL DESCRIPTION

SECTION I

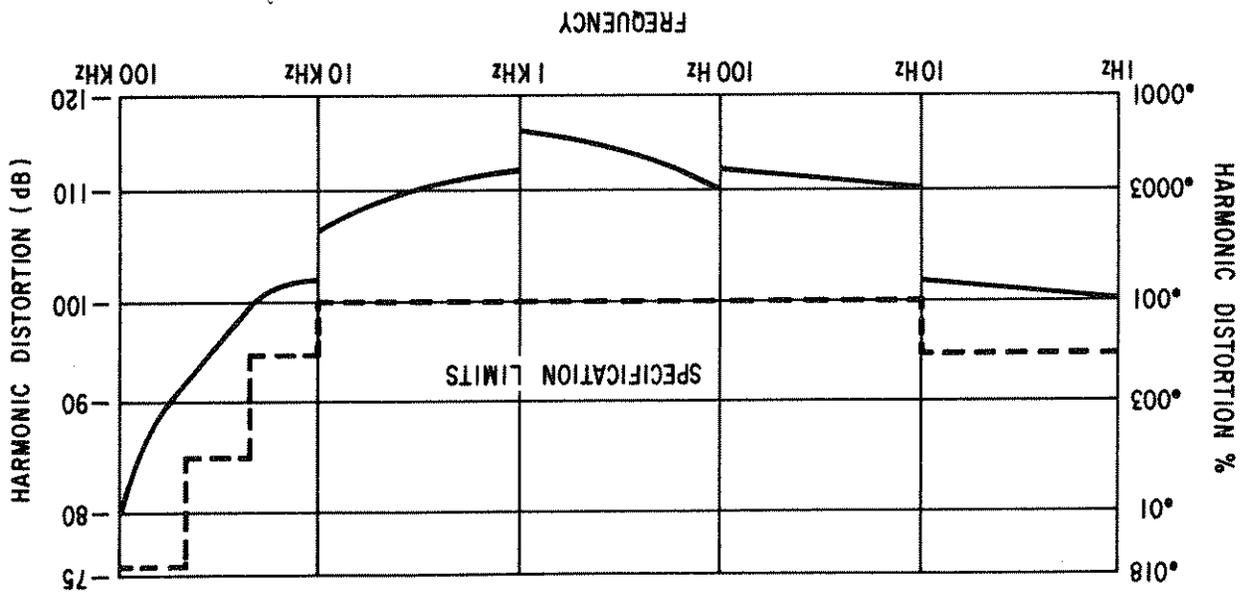

Figure 2. Typical Output Distortion

## SECTION 2

### OPERATION

#### 2.1 INTRODUCTION

This section describes the basic operation of the Model 4500. It includes the proper ac requirements, the recommended turn-on procedure and a detailed explanation of all operating controls.

#### 2.2 POWER REQUIREMENTS

The Model 4500 is designed to operate from a single phase, 50-60Hz ac power source of 90-132 volts or 180-264 volts. A LINE selector switch on the rear panel selects the desired voltage range. The ac power receptacle is a standard 3-pin connector, and complies with the European I.E.C. standard. A detachable 3-wire line cord is provided with the instrument. The fuse receptacle contains a 1/16 ampere slow blow fuse for 120 volt operation, or a 1/32 ampere slow blow fuse for 240 volt (overseas) operation.

#### 2.3 TURN-ON PROCEDURE

- a. Set the LINE switch for the correct voltage range.
- b. Make sure the POWER switch is in the off position.
- c. Plug the line cord into the unit and into an ac outlet.

#### WARNING

The chassis of this instrument is connected to ground. For safety purposes, connect the line cord to a grounded, 3 terminal ac outlet.

- d. Turn the POWER switch on, and allow the unit to warm up for several minutes.

#### CAUTION

Because of the potentially dangerous voltages that exist within the unit, the cover of this instrument should not be removed when the instrument is connected to an ac power source.

#### 2.4 CONTROLS AND CONNECTORS (see Figure 3)

FRONT PANEL:

1. POWER: On-Off pushbutton switch with power-on indicator LED.

Attenuator Volts rms Range

0dB	220mV to 7V
20dB	22mV to 700mV
40dB	2mV to 70mV
60dB	220µV to 7mV

To optimize the resolution of adjustment, use the lower of two attenuator settings (i.e. if the application requires a 500mV rms signal, use the 20dB setting rather than the 0dB setting). The INVERTED (180°) OUTPUT is fixed at 7 volts rms. The output impedance of the INVERTED OUTPUT is 600 ohms ±1%.

FLOATING GROUND OPERATION

The CIRCUIT GROUND switch allows you to "float" or isolate the oscillator circuit or signal ground (  ) from the chassis or earth ground (  ). The maximum allowable dc isolation is 100V.

Set the oscillator frequency to 1kHz. Connect the ACVM to the MAIN OUTPUT. With the VOLTS RMS control turned up to maximum, the MAIN OUTPUT should be greater than or equal to 7 volts rms. Turn the VOLTS RMS control counterclockwise (minimum). The MAIN OUTPUT should drop to less than 220mV. Turn the

MAIN OUTPUT AMPLITUDE

Connect the frequency counter to the MAIN OUTPUT and verify that the frequency accuracy is within +10% of the FREQUENCY Hz setting, between 1Hz and 100kHz.

FREQUENCY ACCURACY

Turn the AMPLITUDE vernier completely clockwise (CW). Adjust the rear panel screwdriver control labeled "DC OUTPUT LEVEL MAX" for a reading of 0 volts.

Connect the DVM to the MAIN OUTPUT. Turn the AMPLITUDE vernier completely counterclockwise (CCW). Adjust the rear panel screwdriver control labeled "DC OUTPUT LEVEL MIN" for a reading of 0 volts.

DC LEVEL ADJUSTMENTS

FREQUENCY Hz; 1kHz (MULTIPLIER X1K, VERNIER set at zero)  
AMPLITUDE; ATTENUATOR (dB) set for 0 (zero), VOLTS RMS set for maximum CW  
CIRCUIT GROUND; Chassis  
WAVEFORM: sine wave

Allow the oscillator to warm up for at least 30 minutes, then set the controls initially to the following:

For the equipment required, see Section 5.2 on page 15.

3.2 PROCEDURE

Because of the potentially dangerous voltages that exist within the unit, the cover of this instrument should not be removed when the instrument is connected to an ac power source.

CAUTION

The following procedure should be used to verify the oscillator is operating within specifications, both for incoming inspection and for routine servicing. Tests should be made with the cover in place. The procedure given below should be followed in sequence. Familiarize yourself with the initial set-up and operating procedures outlined in Section 2.

3.1 INTRODUCTION

INCOMING ACCEPTANCE AND ROUTINE PERFORMANCE TESTS

SECTION 3

Adaptive Sweep	off
Display	clear write
Frequency	1kHz
Amplitude Mode	LOG dB/div
Amplitude Ref Level	0 (zero)
Input Sensitivity	+20dB (10V)
Resolution Bandwidth	100Hz
Freq Span/div	0.5kHz
Sweep Time/div	1 sec
Sweep Mode	repetitive

2. Set switch SI (Figure 5) to the "Input" position. Adjust the 4500 frequency to correspond to the twin tee null frequency.
3. Adjust the Input Sensitivity vernier on the analyzer to obtain a 0dB reference at the fundamental frequency.
4. Switch SI to the "Output" position. Adjust the frequency of the 4500 to null the fundamental frequency.
5. Increase the Input Sensitivity in dB steps until the harmonic components are visible.

The dB level of each harmonic component is the sum of the dB below the Odd reference level on the display, plus the change in the Input Sensitivity level, in dB.

To compensate for loss through the twin tee filter, add +9dB to the second harmonic component and +5dB to the 3rd harmonic component.

For example, if the 2nd harmonic is -118dB,

$$-118\text{dB} + 9\text{dB} = -109\text{dB}$$

Total harmonic distortion may then be calculated as follows:

$$\text{T.H.D. (dB)} = 20 \log \sqrt{\log^{-1} \frac{10}{2nd} + \log^{-1} \frac{10}{3rd} + \dots + \log^{-1} \frac{10}{nth}}$$

$$= 10 \log \sum \log^{-1} \frac{10}{dn} ; n = 2nd \text{ to } nth \text{ harmonic}$$

Where dn = Value of the nth harmonic in dB.

or,

$$\text{T.H.D. (\%)} = 100 \sqrt{\sum \left[ \log^{-1} \frac{10}{dn} \right]} ; n = 2nd \text{ to } nth \text{ harmonic}$$

Where dn = Value of the nth harmonic in dB.

The AVC system is shown in Figure 7. The oscillator loop output signal in Figure 6 is fed to peak detector diode CR12 and the voltage divider formed by R181 and Q199. Q199 is a FET operated as a voltage controlled resistor. The peak detector charges its capacitor to the plus peak value of the sine wave and is fed to one input of U211, the Detector Buffer. A difference or error voltage proportional to the difference between the reference and detected value is produced on the output of U211. This error voltage is fed to U193, the AVC amplifier, for additional filtering and dc gain. The AVC amplifier output feeds the AVC FET Driver Amplifier U196 which in turn drives the gate of Q199.

This control loop varies the voltage dividers loss there by controlling the gain of U174 in the oscillator loop.

### 4.2 AVC OPERATION

The signal on the common point of the bridge T capacitors is lagging the oscillator loop output signal by 90°. This signal is buffered by amplifier U143 and fed to the frequency vernier (R140) and the band calibration potentiometers (R110-R114).

The INVERTED OUTPUT is derived from the oscillator loop.

The MAIN OUTPUT is provided by U251 which is fed from the VOLTS RMS control potentiometer (R245).

The network R value to ground is set by the FREQUENCY Hz dial and the two C values are selected by the FREQUENCY MULTIPLIER switch (S110).

The transfer function of the bridge T network is that of a notch filter. Degenerative feedback around U158 is through the notch filter. Regenerative feedback is provided by U174 to the bottom of the network. At all frequencies, except the notch frequency, the degenerative feedback is greater than the regenerative feedback, the degenerative feedback is balanced out by the regenerative feedback and is slightly in favor of the regenerative feedback. At that frequency the loop will oscillate. The regenerative gain is controlled by the Automatic Voltage Control (AVC) to maintain the oscillation at its proper amplitude.

It consists of two feedback loop systems, one to produce the sine waves and one to maintain stable amplitude.

The Model 4500 oscillator is a true RC sinusoidal oscillator designed for ultra low waveform distortion and flat amplitude response.

A simplified diagram of the oscillating loop is shown in Figure 6.

### 4.1 THEORY OF OPERATION

## CIRCUIT DESCRIPTION

### SECTION 4

## SECTION 5

### CALIBRATION

#### WARNING

This calibration procedure should be performed by qualified personnel only. It is strongly recommended that extra precautions be taken when working with exposed circuitry, and that only insulated probes and tools be used.

#### 5.1 INTRODUCTION

The following procedure is provided for the calibration and adjustment of the Model 4500 in the field. Adherence to this procedure should restore the Oscillator to its original performance specifications. If the Oscillator cannot be calibrated by the procedure given, see Section 6, Maintenance, or consult our Factory Service Department. For the location of all test points and adjustable components, see Figure 8.

#### 5.2 CALIBRATION PROCEDURE

See Section 2 for the correct turn-on procedure. Allow the instrument to warm up for at least 30 minutes.

#### Required Test Equipment:

1. Oscilloscope: bandwidth of at least 1MHz, vertical sensitivity; 10mV/cm, ac/dc coupled.

2. DC Voltmeter: zero to  $\pm 15$  volts.

3. AC Voltmeter: frequency range less than 1Hz to greater than 100kHz, to measure between zero and greater than 7 volts rms, better than 3% accuracy.

4. Amplitude Flatness Measuring Equipment:

a. RMS Voltmeter that will measure ac voltage variations of less than 0.05dB (0.6%) from 1Hz to 100kHz.

OR

b. High Frequency Thermal Converter (Fluke Model A55) and either a DC Differential Voltmeter (Fluke Model 895A), or a DC Null Detector (Fluke Model 845A) with a stable dc reference supply.

5. Spectrum or Wave Analyzer: to measure harmonic components down to 0.001% (-100dB).

6. Frequency/Period Counter: accuracy better than 1%, 1Hz to 100kHz.

Set the controls initially to the following:

FREQUENCY Hz; 1kHz (MULTIPLIER X1K, VERNIER set at zero)  
AMPLITUDE; CHASSIS  
CIRCUIT GROUND; CHASSIS  
WAVEFORM: sine wave

frequency and adjust C118 for the correct AVC voltage at TP4. The counter reading should be 1000  $\pm$  2 digits.

The AVC voltage should remain the same as on X100 band  $\pm$  0.2V.

Set the dial to 10. Adjust C178 for the correct frequency and C170 for the correct AVC voltage at TP4. The counter reading should be 1000  $\pm$  2 digits.

Again, the AVC voltage should remain the same as on X100 band  $\pm$  0.2V.

Due to interaction, repeat step 5.7.

### 5.8 DIAL CONFORMITY CHECK

Set the MULTIPLIER to X100. Set the frequency counter for period operation.

Dial Setting	Reading Range
--------------	---------------

Min. Norm Max.

1.5	6200 - 6666 - 7133
2.0	4650 - 5000 - 5350
2.5	3720 - 4000 - 4280
3.5	2657 - 2857 - 3057
4.0	2325 - 2500 - 2675
5.0	1860 - 2000 - 2140
6.0	1550 - 1666 - 1783
7.0	1328 - 1428 - 1528
8.0	1162 - 1250 - 1337
9.0	1033 - 1111 - 1188

### 5.9 DISTORTION ADJUSTMENT

Refer to "OUTPUT DISTORTION" in Section 3, page 10, for the correct test set-up and procedure. Perform steps 1 through 5. Adjust R208 for a minimum 2nd harmonic component. Also, at 100kHz adjust C152 for a minimum 2nd harmonic component.

The total harmonic distortion, as defined by equations 1, 2 or 3 on page 11, should be greater than or equal to -100dB, or less than or equal to 0.001%.

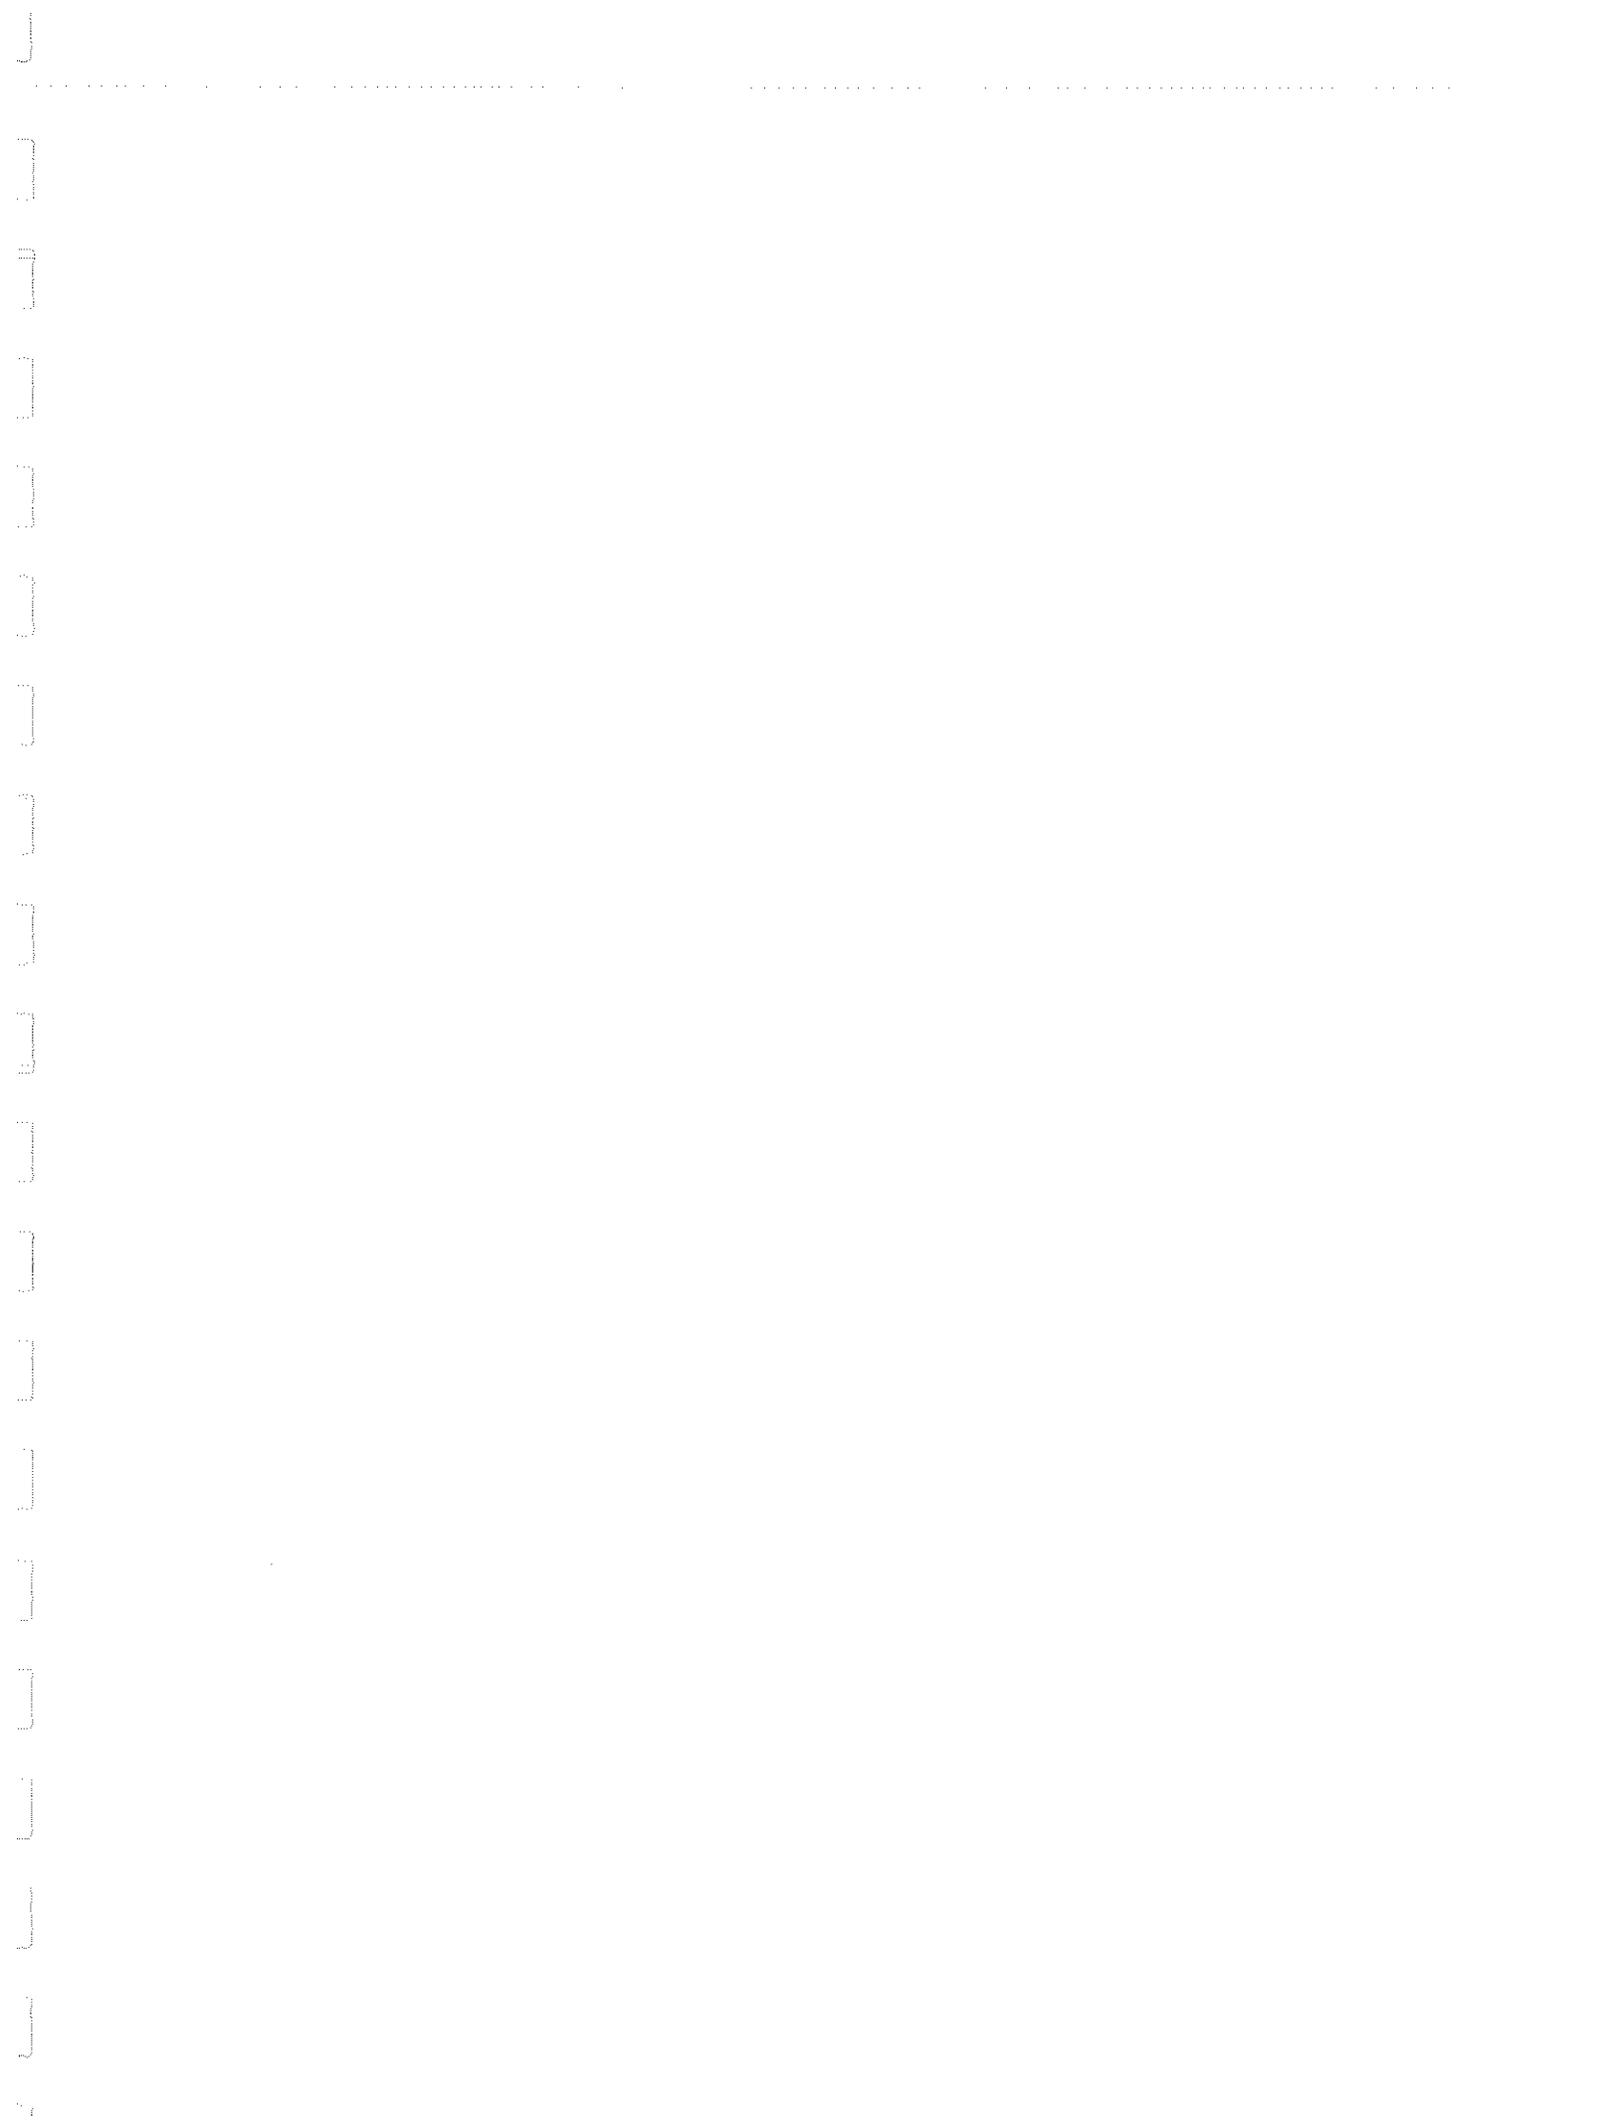

### 5.10 SQUAREWAVE CALIBRATION

Set the frequency to 1kHz (1 X1K). Connect the scope to the 50 ohm MAIN OUTPUT with 3 feet of 50 ohm cable. Set the output AMPLITUDE for maximum amplitude. Select the sinewave waveform. Set the scope gain for 5V/cm.

Note the peak to peak amplitude.

Switch to the squarewave waveform. Adjust R230 for a squarewave amplitude equal to the peak to peak sinewave amplitude.

Connect the DVM to the MAIN OUTPUT (50 ohm). Adjust R232 for a dc level of less than  $\pm$  1mV.

SECTION 6

MAINTENANCE

WARNING

This calibration procedure should be performed by qualified personnel only. It is strongly recommended that extra precautions be taken when working with exposed circuitry, and that only insulated probes and tools be used.

IT IS EXTREMELY IMPORTANT TO SHUT THE POWER SWITCH OFF AND DISCONNECT THE LINE CORD FROM THE POWER SOURCE BEFORE REPAIRING OR REPLACING COMPONENTS.

6.1 INTRODUCTION

Before trouble-shooting, it should be determined if the normal adjustments mentioned in Section 5 will correct the problem. The trouble-shooting of the oscillator will be simplified if there is a basic understanding of the oscillator's operating theory as described in Section 4. Simplified diagrams are provided in the Circuit Description that appreciably reduce the learning time and minimize the need for using the complete circuit diagrams.

6.2 MAINTENANCE PROCEDURE

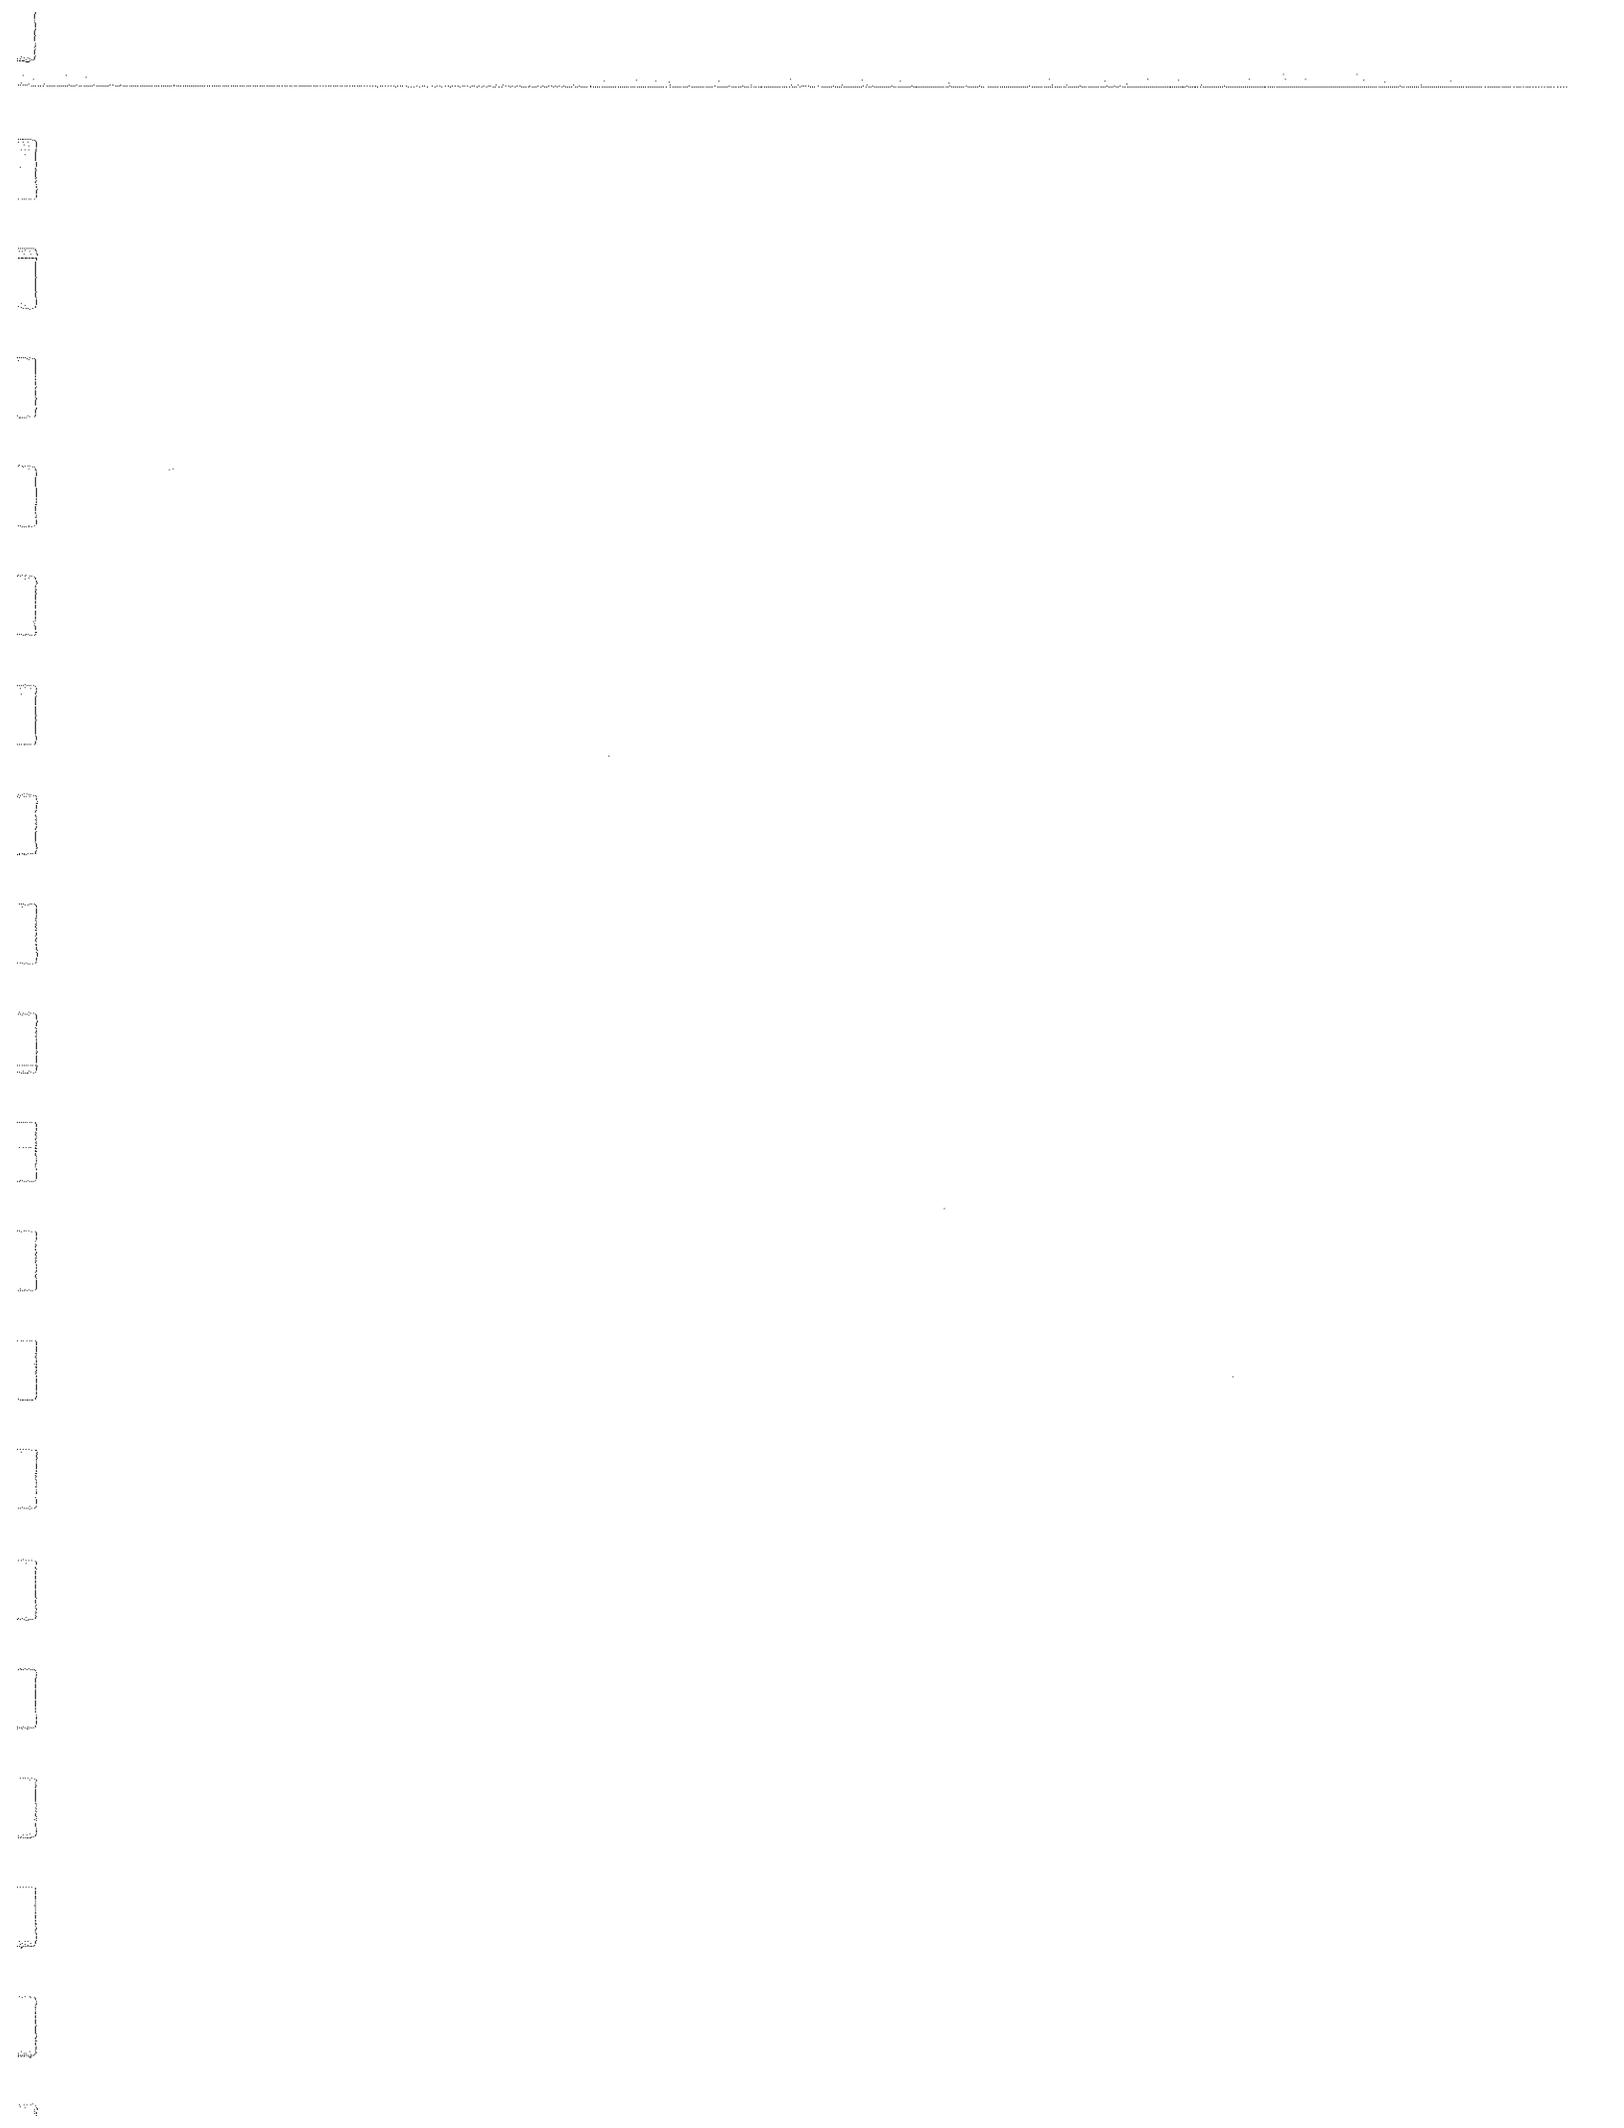

See Section 2 for the correct turn-on procedure. Allow the instrument to warm up for at least 30 minutes.

For the equipment required, see Section 5.2 on page 15.

Set the controls initially to the following:

FREQUENCY Hz: 1kHz (MULTIPLIER X1K, VERNIER set at zero)  
AMPLITUDE: ATTENUATOR (dB) set for 0 (zero), VOLTS RMS set for maximum CW  
CIRCUIT GROUND: Chassis  
WAVEFORM: sine wave

Use the trouble-shooting flow chart to localize the source of the problem.

PARTS LISTS, SCHEMATICS AND BOARD LAYOUTS

SECTION 7

Any engineering modifications will be found on a Modification Sheet inside the rear cover of this manual.

The part numbers listed are either the actual parts used or direct replacement.

7.2 ORDERING UNLISTED PARTS

When ordering parts from Krohn-Hite that are not listed, include the instrument model number (Model 4500), instrument serial number, a description and location of the part.

7.1 ORDERING INFORMATION

When ordering parts from Krohn-Hite, specify the instrument model number (Model 4500), instrument serial number, schematic reference designation (ie; R, G, CR etc..) and the manufacturer's part number (see the list below for the manufacturer's abbreviation and FSCM number).

Address all inquiries to your local Krohn-Hite Sales Representative or directly to Krohn-Hite.
