Section 1

INTRODUCTION

1-1. Scope of This Manual

This publication provides operation and service instructions for the Rod-L Electronics Inc. Ground Continuity Test Instruments. (It will refer to Model M25, though the M30, M35, and M10 all operate the same. The model number refers to the amount of current it is capable of outputting). The manual is divided into six sections.

- Section 1 - Introduction (capabilities and specifications)
- Section 2 - Installation and Operation
- Section 3 - Theory of Operation
- Section 4 - Service and Calibration
- Section 5 - Options
- Section 6 - Parts Lists, Schematics, Diagrams

1-2. Ground Continuity Tester General Description and Test Features

The Rod-L Ground Continuity Test Instruments, Models M25, M30, etc., are rugged, self-contained testers designed for both laboratory and production use. Its purpose is to provide a means for evaluating the ground continuity between a unit's chassis and the ground from the AC power-in cord. This ground must be able to effectively shunt any accidental "leakage" current, usually produced by accidental high voltage spikes, to earth ground.

Certification agencies usually require a 1 ampere ground continuity test to ensure that a ground is capable of diverting any leakage current without getting damaged. Several European and Canadian agencies, including B.S.I., V.D.E., and I.E.C., require a 25 ampere ground continuity test.

The Model M25 Ground Continuity Tester applies a 25 ampere current to the DUT (Device Under Test) for a duration of time, preset from 1 second to 90 seconds. The DUT is plugged into the front panel receptacle (or special rear panel connector option). The total resistance in the ground circuit is measured and displayed on the front panel of the Ground Continuity Tester. Test limits for total resistance are preset by the user via a rear panel control. When the DUT is defective, automatic circuitry turns off the current and meter, turns on a FAIL lamp, and activates an audible alarm. This electronic shutdown circuit turns off the

current within 2ms (two milliseconds) after a fault. These audible and visual alarms must be manually reset at the front panel, or by a Remote Control Option.

Important physical, electrical, and environmental specifications are given in Table 1-1.

1-3. Product Specifications (Table 1-1)

Table 1-1: Model M25 Specifications

Test Voltage and Current
at 0.1Ω load; 3 VAC RMS, 25 A RMS, 50/60 Hz

Voltage Shutdown
Within 2 milliseconds after a fault or end of test is detected (electronic shut down circuits)

Test Time
1 second to 90 seconds (adjustable)

Initial Turn-On Period
Allow 5 seconds warm-up

Ohm Meter
0 - 0.15Ω, ±5% F.S. accuracy

Ammeter
Up to 40 amps (user specified) ±5% F.S. accuracy

Input Power
115/230 VAC, 44-66 Hz., 360 watts, max

Environmental Operating Temperature
0° to 50° C, 32° to 122° F

Exterior Color
Mint grey / Olive grey

Weight
35 lbs (13.5 kg) net

Dimensions
16.75 × 13.25 × 5.5 inches (43 × 34 × 14 cm)

1-4. Safety Features

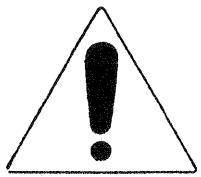

- A) Loss of Ground connection terminates test cycle
- B) Front panel receptacle accepts 3-pronged power cord from DUT providing maximum safety and significantly reduces time required to perform the test
- C) Recessed START button
- D) Visual alarm at failure
- E) Audible alarm at failure
- F) Fast electronic shut down of voltage
- G) Hard RESET after failure required to perform next test
- H) Complete discharge of Device Under Test (DUT)

1-5. Supplied Equipment

- A) Ground Continuity Tester, Model M25, M30, M35, or M10
- B) Power Cord, three pronged, 6 ft
- C) High Current Ground Sense cable, 18 in
- D) HV Interface Cable (interfaces to Hipot)
- E) Operation/Service Manual
- F) Extra fuse set for the alternate AC supply voltage

Section 2

INSTALLATION AND OPERATION

The exclamation point within a triangle is intended to tell the user that important operating and servicing instructions are in the papers that are provided with the equipment.

WARNING

Verify that the voltage selector switch is positioned and the correct power supply cord is selected to match the voltage source.

WARNING

This product is shipped with a high voltage mating plug and cap installed on the rear panel HV OUT/INTERFACE connector. To reduce the risk of shock, this plug and cap must be used whenever the high voltage interface cable is not installed.

In addition, the high voltage interface cable must only be used when both ends are terminated at their respective equipment connectors. To reduce the risk of electric shock, the equipment must not be operated with one end not terminated.

2-1. General Information

This section contains the recommended procedures for unpacking, inspection, installation, operation, storage, and reshipment.

2-2. Unpacking and Inspection

A shipping carton that appears damaged should be inspected and unpacked with the carrier's agent present. Inspect the instrument for damage (scratches, dents, broken knobs or meters, etc.)

If the instrument is found to be damaged upon receipt, notify the carrier and Rod-L Electronics immediately. Retain the shipping carton and the padding material for the carrier's inspection, and for return shipment.

2-3. Installation

The Rod-L Ground Continuity Test Instrument is suitable for either bench or rack mounting. To rack mount the instrument, use Option 15A. The instructions for rack mounting are on page 33.

2-4. Power Requirements

The Ground Continuity Tester requires a power source of either 115 or 230 volts AC, 44 to 66 Hz single-phase. Prior to applying power to the instrument, ensure the AC line voltage selector switch on the Rear Panel is in the appropriate position. Also, the AC power socket to which the Ground Continuity Tester connects must have a functioning safety ground.

To protect operating personnel, NEMA, the National Electrical Manufacturers Association, recommends that the instrument panel and cabinet be grounded. The Ground Continuity Tester is equipped with a 3-conductor power cord, which, when plugged into an appropriate receptacle, grounds the instrument. The offset pin on the 3-prong connector is the ground pin.

2-5. Storage

It is strongly recommended that the Ground Continuity Tester be packed as if for reshipment. Environmental conditions during storage and reshipment should be as follows:

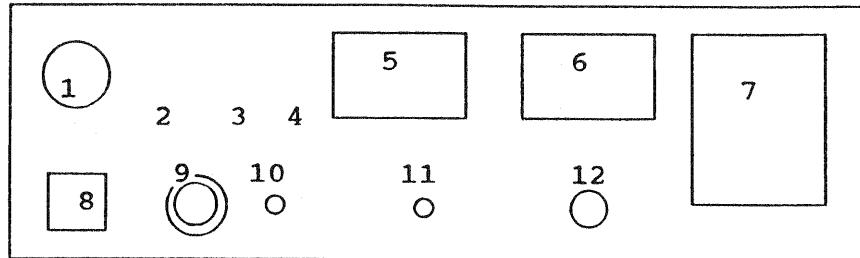

- A) Maximum temperature: 167°F (75°C)
- B) Minimum temperature: -40°F (-40°C)

2-6. Repackaging for Shipment

If possible, use the original shipping container and packing materials. Otherwise:

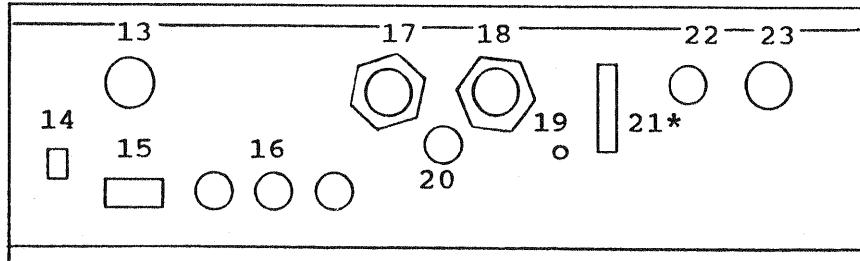

- A) Wrap the Ground Continuity Tester in heavy paper or plastic before placing it in the shipping container.
- B) Use plenty of packing material around the instrument, and protect the front panel with cardboard or plastic bubble packing. Protect the instrument with two inch rubberized foam pads placed along all surfaces of the instrument, or with a layer of excelsior about 6 inches thick packed firmly against all surfaces of the instrument.

Figure 2-1: Ground Continuity Tester Front Panel Controls

1. Alarm emits audible signal on failure
2. READY lamp comes on at power up
3. TESTING lamp on during a test
4. FAIL lamp on if a test fails
5. Current (I) meter indicates current (in AC Amps)
6. Ohm (R) meter provides direct Resistance reading of DUT's ground loop
7. HV Output Block receptacle for DUT's 3-pronged AC power line
8. LinePower switch turns on and indicates line power input
9. START switch initiates Ground Continuity Test if instrument is grounded properly and not already indicating a ground-test failure
10. RESET button resets Ground Continuity Tester
11. A/B switch chooses Function; Ground Continuity Test only or Ground Continuity Test and Hipot Test
12. Chassis Ground Sense for DUT chassis ground connection

Figure 2-2: Ground Continuity Tester Rear Panel Controls

13. Low Line Switch S5 compensates for Low Line Voltage inputs; normal, -8%, or -16%
14. Voltage Selector Switch chooses 115VAC or 230VAC input; be sure to install correct fuses
15. AC line power in receptacle
16. AC Fuses F1/F2 3A @ 115VAC, 2A @ 230VAC; F3 .5A @ 115/230VAC
- 17.* HV Out connector (*Optional) hipot HV for Leakage Tester(LT) use
18. HV Interface connector for AC Hipot Interface
19. Ground jack for connecting chassis' of other testers
20. Ground Sense jack connects to Ground Sense of Hipot Tester
- 21.* Remote connector (*Optional) for remote interface
- 22.* Current In jack (*Optional) for input of current from the LT
23. Ohms Trip pot R5 calibrates Ohms Trip setting

- C) Use a strong, well-sealed shipping container (350 lb/sq in. bursting test).
- D) Mark the container "FRAGILE - DELICATE INSTRUMENT."

2-7. Operating Controls

The Front panel and rear panel controls are shown in Figures 2-1 and 2-2.

WARNING

This instrument to be used ONLY in THREE WIRE GROUNDED OUTLETS. It is recommended that periodic checks of the outlet and the ground wire be made to ensure operator safety.

2-8. Initial Installation and Power-Up

The Ground Continuity Tester is shipped configured for 115 VAC operation. Appropriate fuses (1.5 ampere) are also provided for 230 VAC operation. Before applying 230 VAC power to the instrument, perform the following:

CAUTION

Changing Fuses: Turn off the Ground Continuity Tester and DISCONNECT THE POWER CORD. Then install the proper fuses. Otherwise, damage to the instrument and/or operator could result.

2-9. Operational Check

This is an operator oriented procedure which allows operational check of the Rod-L Ground Continuity Tester without test equipment. Refer to Section 4 of this manual for a complete calibration procedure.

Place the instrument in a sturdy position, preferably on an insulated surface, with all surrounding metal/conductors grounded. Position the power cord so as to avoid being walked on or pinched by other equipment.

- A) Set LINE POWER switch to OFF.

- B) Validate that the fuses are the proper values.
- C) Verify Input Line Voltage Select Switch position.
- D) Set the OHMS TRIP control to full clockwise position.
- E) With an AC voltmeter, check the primary power line for normal line voltage conditions.
- F) Set the VOLTAGE ADJ switch on the rear panel to appropriate position if the AC input is low line.
- G) Connect AC Power Cord between the AC receptacle on the rear panel and an AC power source.
- H) Set LINE POWER switch to ON.
 - a) The lamp should light.
 - b) The green READY lamp should also illuminate.

NOTE: If the power ON lamp remains off, check for proper AC line voltage.

- I) Insert the banana plug of the High Current Chassis Ground Cable into the Chassis Ground Sense banana jack. Connect the clamp of that cable to any exposed metal part of the Ground Continuity Tester.
- J) Insure that "OHM TRIP" on the rear panel is set to "10," the maximum.
- K) Push the START button.
 - a) The Testing Lamp should come on for approximately 5 seconds.
 - b) Current Meter should read approximately 30 amps.
 - c) Ohmmeter should read less than $.01\Omega$. Keep in mind, this reading is with NO LOAD. Record this reading on page 13, Section 2-11.
- L) Set "Total Ohm Trip" pot to the minimum, "0."
- M) Push the START button.
 - a) The alarm should sound.
 - b) The red FAIL lamp should illuminate.

NOTE: If this setting is left as is, turning the M25 off and then on again may cause it to fail as soon as it is turned on.

- N) Press the RESET button.
 - a) The alarm should go off.
 - b) The red FAIL lamp should go off.

- o) If the above conditions are met, the Ground Continuity Tester is operating properly. If your normal operating voltage is different from what is specified above, refer to Set Up Procedures (4-4), page 25.

2-10. Total Resistance Trip Set

The BSI standard states that the resistance to be measured shall not exceed $(0.1 + R)\Omega$, where R is the resistance of the supply cord. The high current grounding cable must also be considered, and this resistance was measured in Section 2-10, K, c) on page 12.

Each division on the scale of the Total Current Trip pot represents approximately $.015\Omega$, and this scale is non-linear to the pot.

For accurate failure points, a known value of resistance should be inserted into the Continuity Loop. The trip point pot can then be adjusted from above until a failure is indicated, or in other words, while the test is running, set the trip point pot high enough so that there is no failure, then turn the pot slowly down until a failure occurs.

2-11. DUT (Device Under Test) Ground Continuity Test

- A) Plug the power cord of the DUT into the 3-pronged receptacle on the front panel of the Ground Continuity Tester.
- B) Insert the banana plug of the High Current Chassis Ground Cable into the *Chassis Ground Sense* banana jack.
- C) Connect the clamp of that cable to any exposed metal part of chassis of the DUT. Make sure connections are solid.
- D) Push the START button.
 - a) The Testing Lamp should come on.
 - b) If the total resistance of the DUT does not exceed the setting of the Trip pot, the test will run approximately 5 seconds.
 - 1) The Ammeter will indicate the current through the Ground Loop.
 - 2) The Ohmeter will indicate the resistance of the Ground Loop of the DUT.
 - c) If the total resistance of the DUT is higher than the Trip pot setting, a failure indication will be given, both audible and visual.

- d) To test devices that do not have a 3-pronged supply cable, make a suitable grounding cable by using 3 layers of 3/16" flat tinned copper braid tubing, and 2 (each) 25amp battery clamps. To perform a Ground Continuity Test under these conditions:
- 1) Connect banana plug of High Current Cable to the Ground Continuity Tester banana jack.
 - 2) Connect clamp to the chassis of DUT.
 - 3) Connect one clamp of the cable just made to DUT ground, and other clamp to the chassis of the Ground Continuity Tester. Proceed with Step 3-13,D. (Remember to compensate Trip point for resistance of the newly made cable).

2-12. Test Time Adjustment Procedure

The Test Time Adjustment potentiometer is factory set for 5 to 7 seconds. Reset this control as necessary in accordance with the regulatory agency suggested test time for the DUT.

To reset the test time duration, proceed as follows:

- A) Turn OFF power to the Ground Continuity Tester.
- B) Remove top cover and locate Test Time Adjustment potentiometer, R22 on the A22 Control Logic PCB.
- C) Set the Ground Continuity Tester up for a Ground test; either chassis self-test, or with a device to be tested.
- D) Reapply power to the Ground Continuity Tester.

CAUTION

Do not touch any of the other potentiometers on the PCBs. Otherwise, the calibration of the instrument will be destroyed.

- E) Use a stopwatch to time how long the TESTING lamp remains lit. By adjusting R22 on the A22, and timing the TESTING lamp duration with the stopwatch, any Test duration can be set between 1 second and 90 seconds.

2-13. Automatic Test Procedure: Using the Ground Continuity Tester with a Rod-L Hipot

See the drawings at the rear of this manual, #s 01075-01 and 01076-01. One of these drawings should enable setting up of a Ground Continuity Tester and Hipot Tester for use in tandem.

Connect the Remote Control Cable (with 25p D Sub miniature connector) to the Ground Continuity Tester, and a remote operating device if the Ground Continuity Tester is equipped with Option 01 or 19.

Make sure that the Ground Continuity/Hipot Tester Interface Cable (4pin LGH connector) is in place.

Ensure the Testers are connected to the same AC Line Power source.

Turn AC power switch of the Ground Continuity Tester on first.

NOTE: If the Hipot is turned on first, the Hipot Tester may immediately start a test when the Ground Continuity Tester is turned on, and high voltage will appear on both output receptacles.

Then turn on the power switch of the Hipot Tester.

The DUT (Device Under Test) should be plugged into the Ground Continuity Tester receptacle for sequential testing, i.e., Ground Continuity Test first, and then the Hipot Test.

If the Hipot Test only is preferred, the test must be initiated at the Hipot Tester. (The DUT can still be plugged into the Ground Continuity Tester).

A failure of the Ground Continuity Test will not allow the Hipot Test to start. If a failure occurs in the Ground Continuity Test or the Hipot Test, a RESET on the Ground Continuity Tester must be initiated before any further testing can be done. If the Hipot Tester is equipped with the Automatic Reset Option, when a failure occurs in the Hipot Test only, the Tester will automatically reset in 3 seconds.

If the Hipot Tester's Chassis Ground voltage is not connected to BP-2, the Rear Panel Banana Jack of the Ground Continuity Tester, the READY light of the Hipot Tester should not come on, and no Hipot Test can be initiated from the Ground Continuity Tester. If the Hipot Tester's chassis Ground voltage is connected to BP-2, the total safety Ground return, from the DUT to the Hipot Tester, is tested, and the READY light should be on if this resistance is

less than the Hipot Tester's setting (0.5Ω standard). It is assumed that the Hipot Tester controls are already set up according to the respective Operation Manual.

Push the START button on the Ground Continuity Tester.

The READY light of the Hipot Tester should go off since the Safety Ground Return Test from the DUT is taken over by the Ground Continuity Tester using the relays K1 and K2 (see drawing # 00941-XX, or if none, then 00431-XX). The Safety Ground Return is connected to the Ground Continuity Tester Chassis and the Chassis Ground voltage output through BP-1 is connected to the High Current Transformer.

The TESTING light of the Ground Continuity Tester comes on and the Ground Continuity Test is performed. Should a failure occur, the Ground Continuity Tester has to be manually RESET. No Hipot Tester will be automatically started if that occurs.

Put front panel switch in Ground/Hipot Test position for sequential testing. If Ground Continuity Test only is performed, place the switch in the ground position. Sequential testing, or Ground (Continuity only) Test, will be initiated by starting the Ground Continuity Tester. The Hipot Tester's Chassis Ground voltage must be connected to BP-2, the Rear Panel Banana Jack of the Ground Continuity Tester.

If the Ground Continuity Test performs successfully, the TEST light will go off after the preset time. Then the READY light on the Hipot Tester will go on as the Hipot Tester takes over the Safety Ground Return Test. Because the relays K1 and K2 in the Ground Continuity Tester return to normal position, the Safety Ground Return is connected to the Hipot Tester Chassis through the HV Return wire, and the Chassis Ground voltage output BP-1 is connected to BP-2 where the Chassis Ground voltage of the Hipot Tester is connected.

After about 1 second the Hipot Tester is started automatically from the Ground Continuity Tester. The Hipot Tester test light comes on and continues to perform as specified in the respective manual. Pressing the RESET button on the Ground Continuity Tester can, at any given moment, reset the Hipot Tester.

2-14. Ground Continuity Tester with M488 Tester Set Up

The Ground Continuity Tester to Hipot Tester Interface Cable, and the connection between the M488's Chassis Ground and the Ground Continuity Tester BP-2 Rear Panel Banana Jack should be made as described above in section 2-14.

The Ground Continuity Tester must be equipped with Option 01 Remote Control, and the 25-pin Remote connectors on the rear panels of both instruments must be connected together.

Turn the Power Switch of the M488 on first. Then turn on the Ground Continuity Tester.

The DUT (Device Under Test) should be plugged into the Ground Continuity Tester receptacle for sequential testing, i.e., Ground Continuity Test first, and then the Hipot Test.

Sequential testing will be initiated by starting the M488 Hipot Tester according to the instructions described in the M488 Operations Manual.

The A8 Remote PCB should be adjusted, if needed, for putting out 10 VDC when a 0.1Ω load resistor is used. This is for the M488 monitoring of the resistance. Refer to the Options Section, page 30.

Section 3

THEORY OF OPERATION

3-1. General Introduction

This section concerns the circuit theory for the Ground Continuity Tester. This system was designed to ensure high quality, accuracy, flexibility, and safety of operation.

The Grounding system of any electrical product is important in keeping all operator-accessible dead metal parts grounded so that, should insulation fail, hazardous levels of voltage and current would be shunted to "earth" ground. Of course, electrostatic charges and induced electromagnetic eddy currents would also be "earthered."

The Ground Continuity Tester tests the reliability (in the event of a failure) of a Grounding System in an electrical / electronic product; that is, the current carrying capacity. In this manual, we shall refer to this product as the DUT (Device Under Test). The Ground Continuity Tester supplies a test current amplitude which is sufficiently high to effectively "burn out" weak spots in a DUT's Grounding System. The Ground Continuity Tester test also measures the actual resistivity to assure a sound path for current flow to the "earth" ground.

If this Amp Ground Continuity Test is performed before a Hipot (or High Voltage Potential or Dielectric Withstand) Test, it ensures the safety and protection of users during subsequent hipot and leakage current tests. (25 amps at only 3 volts cannot harm any user).

3-2. Ground Continuity Tester Functional Description

Functionally, the Ground Continuity Tester is divided into 3 sections: the High Current Generator, General Control, and an optional Remote Control.

The High Current Generator consists of an AC transformer (50/60 Hz) specially designed to provide the current needed in the Ground Continuity Test. It is activated through a solid state optically isolated relay during an AC input line zero crossing after the corresponding signal is given by the General Control.

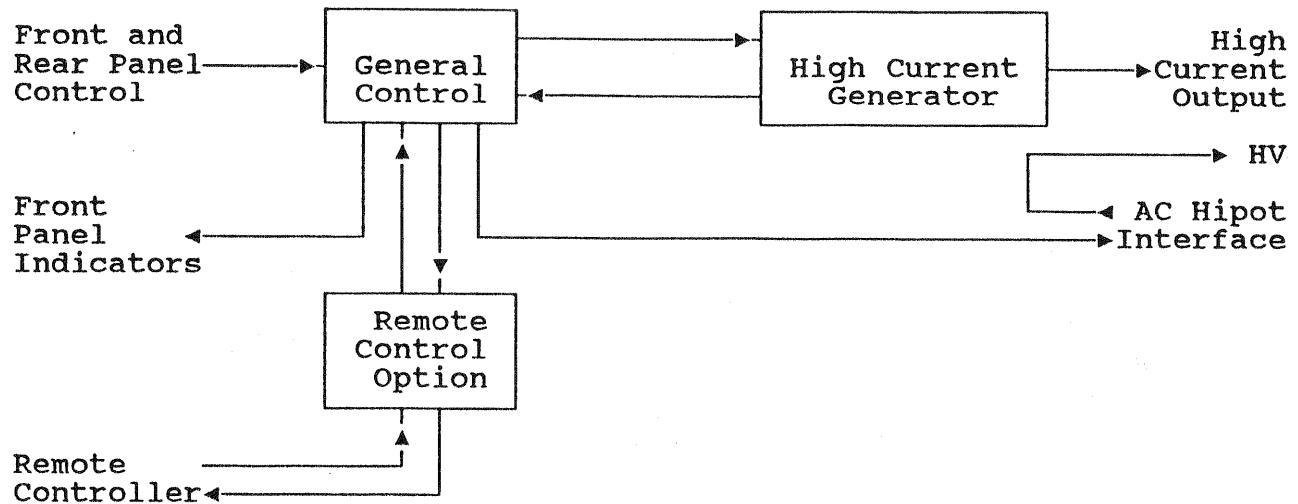

Figure 3-1: Ground Continuity Tester Functional Block Diagram

The General Control performs the coordination of the different activities and monitoring as shown in Figure 3-2. The control can be commanded from the respective front and rear panel controls shown on the left side of the diagram. It takes care of coordinating the different activities and sensing the status of the operation. It provides continuous monitoring through the front panel lights, buzzer, and meters shown on the right side of the figure.

The Remote Option is an isolated interface for most of the control and monitor signals.

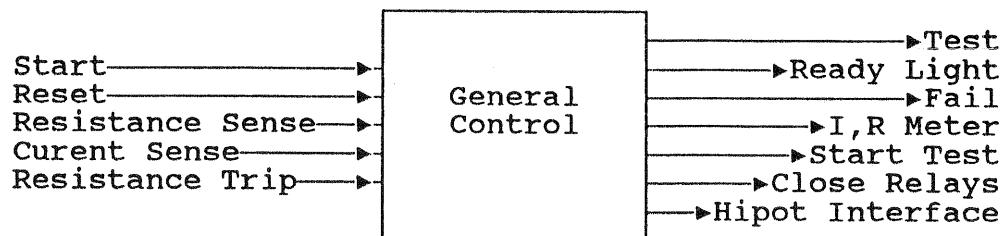

Figure 3-2: General Control Functional Diagram

3-3. Ground Continuity Tester Electrical Description

The Ground Continuity Tester is divided into 2 sections as shown in Figure 3-3. The left side of the diagram is physically separated and contains an A26 Mother PCB, A22 Control Logic PCB, and an A10 Power Supply PCB. It can also contain an A8 Remote

Control PCB. The right side of the figure contains the electrical transformers, relays, and current sense resistors.

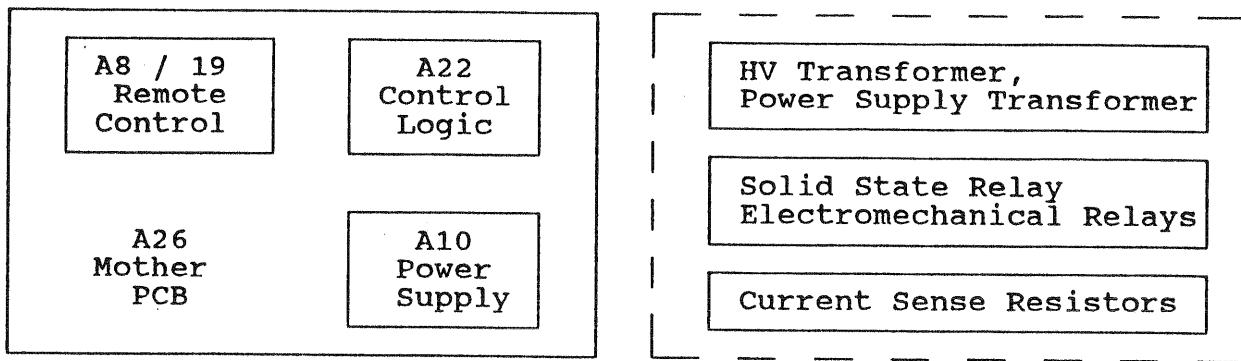

Figure 3-3: Ground Continuity Tester Assembly Diagram

3-4. A10 Power Supply P. C. Board

3-4.1. Description

The A10 generates the regulated +5VDC, +15VDC, and -15VDC power supplies that are used throughout the unit.

3-4.2. Theory

With reference to schematic # 00978-01, the different AC voltages are full wave rectified by U1, 2, and 3, and they are filtered and regulated by VR1, 2, and 3.

3-5. A22 Control Logic P. C. Board

3-5.1. Total Current Detector

The A22 Control Logic PCB receives the voltage from across the current sense resistor set. This resistor set is composed of 8 resistors (on the Ground Continuity Tester, 6-12 on other models), each valued at 2Ω 50W, giving a total resistance of 0.25Ω .

3-5.2. Logic Control

As shown on schematic # 00972-XX, the A22 receives all switch inputs and monitor outputs from the fail comparator. It controls the duration of the test and stops the test when there is an operator reset or fail condition. This PCB keeps the failure signal present until there is a manual reset from the user. It also includes a zero crossing detector using an 18VAC input, and a start generator.

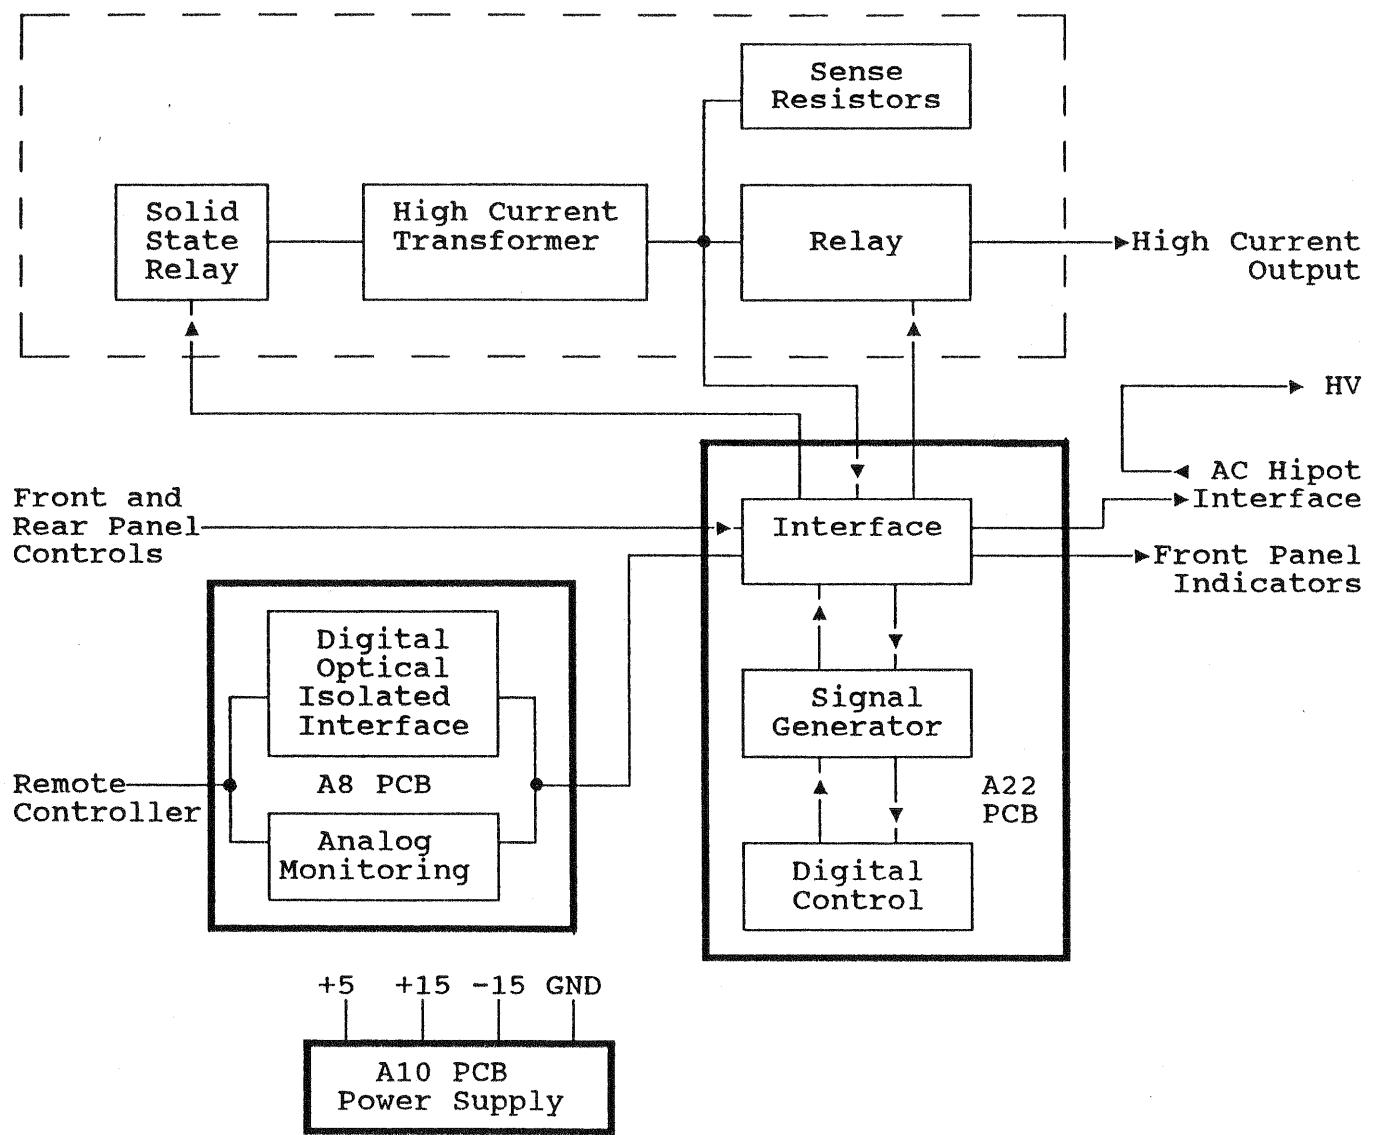

Figure 3-4: Ground Continuity Tester Block Diagram

There are three digital inputs: *START*, *RESET*, and the *FAILURE* from the resistance comparator, U9.

There are status and control outputs: *TEST LIGHT*, *REMOTE TEST*, *FAIL*, *AC HIPOT START*, *AC HIPOT RESET*, *RELAYS*, and an optional pulsing-tone drive.

3-5.3. Theory

Referencing schematic # 00984-XX, with the *START* input from the Edge-card connector Pin 9, two NAND gates (U5, U6) provide a hysteresis buffer. U5-11 (U5, pin 11) provides the *TEST* latch which drives transistor, Q1, to provide a *REMOTE TEST* signal for the Remote Option. U5-11 also drives U7 which drives the *RELAYS* through Edge-card connector Pin D.

The Relays (K1, K2) are high current type, referred to on drawing # 00941-01. When activated, they connect the High Current Transformer to the Output Receptacle, and connect the HV Return on the Front Panel Receptacle Block to the Chassis of the Ground Continuity Tester. When the relays are deactivated, (if the Ground Continuity Tester is interfaced with the Hipot Tester) the high current output is connected to 1.5 VAC Chassis Ground Sense Voltage of the Hipot, and the HV Return is connected to the HV Return of the Hipot. This makes possible performance of a continuous 1 amp Chassis Ground Sense Test during the Hipot Test. It also allows a separate Return, for the high voltage test, from the DUT to the Hipot Tester.

The *START* signal also triggers the *DELAY* timer, U11, for setting up the *RELAYS*, and at the end of the delay, the *START PULSE* timer is triggered. This pulse gates the zero crossing pulses produced by Q8, and triggers the *TEST TIMER*, U11. The duration of the test is controlled by the pot R22. The output of the *TEST TIMER* drives the *TEST LIGHT* through U8 and drives the analog switches in U3 for enabling the monitoring of current and resistance.

The *FAIL LATCH* can be set by the output of the resistance comparator in U9, driving the *FAIL* signal through U7. The *FAIL LATCH* is composed of two NAND gates in U6. The latch can be reset by the *RESET* signal coming through Edge-card connector Pin 5.

The Fail Latch also operates the *SYSTEM RESET* through U10-2 (U10, pin 2). This gate gathers the different signals that can reset the system: the Reset Switch, the Fail Latch, and the Test signal from the Test Timer. The Test signal is fed through a network that produces a pulse at U10-4,5 at the End Of Test, resetting all the timers and the Test Latch. This Reset is also transmitted to the Hipot Tester (when interfaced) through the optical isolator, U2.

At the end of a successful Test, the signal from U5-11 (the Test Latch) goes through a network that produces a pulse at U12-8, triggering a Delay Timer which sets the Hipot before a Start signal is produced by U11. The Delay Timer triggers the Trigger Timer, U11, which produces the Start Hipot signal, through the optical isolator, U1. These timers are reset by the system RESET, as in the above paragraph. C22 is larger than C10 to insure the generation of the Start Hipot signal even if the system Reset is generated by the End Of Test signal only.

The Remote signal at Edge-card connector Pin C can activate the transistor, Q2, when no remote programming is desired, connecting Pin C to +5V. This will put a low level at U3-6 (U3, pin 6) (opening contact C), and a high level at U3-12, (closing contact D). The opposite occurs when the Edge-card connector Pin C is tied to Ground, selecting Remote Programming.

Section 4

MAINTENANCE AND SERVICE

WARNING

These Service Instructions are for use by qualified personnel ONLY. To avoid electric shock, do not perform any servicing other than that contained in the operating instructions unless you are qualified to do so!

4-1. Introduction

This section provides maintenance and service information for the Rod-L Ground Continuity Tester. Included is a list recommended test equipment, trouble shooting procedures, calibration procedures, and adjustment data.

Rod-L recommends that the ground continuity testers be calibrated on a 6 or 12 month cycle at the discretion of the customer based on volume of usage. Under no circumstance should a 12 month cycle be exceeded.

4-2. Equipment Needed

The following equipment will be needed to complete the factory calibration procedures:

- A) Oscilloscope
- B) Digital Multi-Meter (DMM) (Voltage floating input)
(Ammeter RMS reading)
- C) 115 - 230 VAC Line Step Up Transformer
- D) AC Variac
- E) AC Current Sensor (American Aerospace Controls, Inc.
1003A MI-50 or equivalent)
- F) Calibration Standard Resistor 1%: 0.1Ω 50W
(The accuracy of the Ground Continuity Tester ohmometer depends on accurately determining the value of this resistor. Several resistors of close, yet slightly different value are recommended)

4-3. Factory Calibration Procedures

There are five major calibration points on the Ground Continuity Tester. They are:

- A) Meter Mechanical Zero
- B) Current Meter Calibration
- C) Resistance Meter Calibration
- D) Test Time Calibration
- E) Fail Pot Calibration

4-4. Set Up

The equipment should be set up to ensure testing at 115 VAC or minus 1% (low line switch = "Normal"). Remember to set the line switch to 115 or 230 VAC position depending on the AC input line voltage. It is recommended that calibration be done with the same line input voltage as would be used for normal operation. If line frequency is different from 60Hz, remember that required capacitor values will change.

4-5. Meter Mechanical Zero

With the Ground Continuity Tester turned OFF, note the positions of the ohmeter and ammeter pointers on the front panel. They should read 0 ± 1 minor division. If they do not, adjust the null screw.

4-6. Current Meter Calibration

Turn the M25 ON and note that the Ammeter Pointer is at 0 ± 1 minor division. The READY light should be on. If not, trouble shoot the A10 Power Supply PCB or the READY light driver on the A22 Control Logic PCB. Insure that the calibration load (see Section 4-2,F) is connected between the Front Panel Receptacle 25 Amp output and the Front Panel Receptacle HV Return (chassis handle could also be used) through the AC Current Sense as shown in Figure 4-1. Turn the OHM TRIP potentiometer fully CW (clockwise).

Push the START button.

The ammeter should deflect to about 25 amperes. The DVM connected with the AC Current Sensor should agree with the ammeter reading within 3%F.S. (Full Scale). If they don't agree, adjust the pot R25 on the A22 PCB until they do.

Push the RESET button.

4-7. Resistance Calibration

- A) Confirm that the current meter has been calibrated as described in Section 4-6.
- B) Connect the 0.1Ω test load as shown in Figure 4-1, page 27.
- C) Initiate the test cycle and make note of the maximum output current while the test is in progress.
- D) Connect an AC voltmeter between the Front Panel Chassis Ground Sense connector and the ground pin of the Front Panel High Voltage Receptacle (best recommendation is on the inside of the front panel).
- E) Initiate the test cycle and make note of the maximum voltage between these two points (step D).
- F) Using the equation $R = V/I$ — where R is load resistance, V is the voltage measured in step E), and I is the current measured in step C) — calculate the load resistance.
- G) Initiate the test cycle and adjust the pot R21 on the A22 PCB until the reading on the resistance meter agrees with the resistance calculated in step F).

4-8. Test Time Calibration

To set a specific test time, follow the instructions in Section 2-12, page 14.

To check test time limits, turn TEST TIME pot R22 on the A22 Control Logic PCB to minimum (fully CW) and maximum (CCW). Minimum should be 1 second and maximum about 90 seconds. If not, troubleshoot timer or call a Rod-L Applications Engineer for assistance.

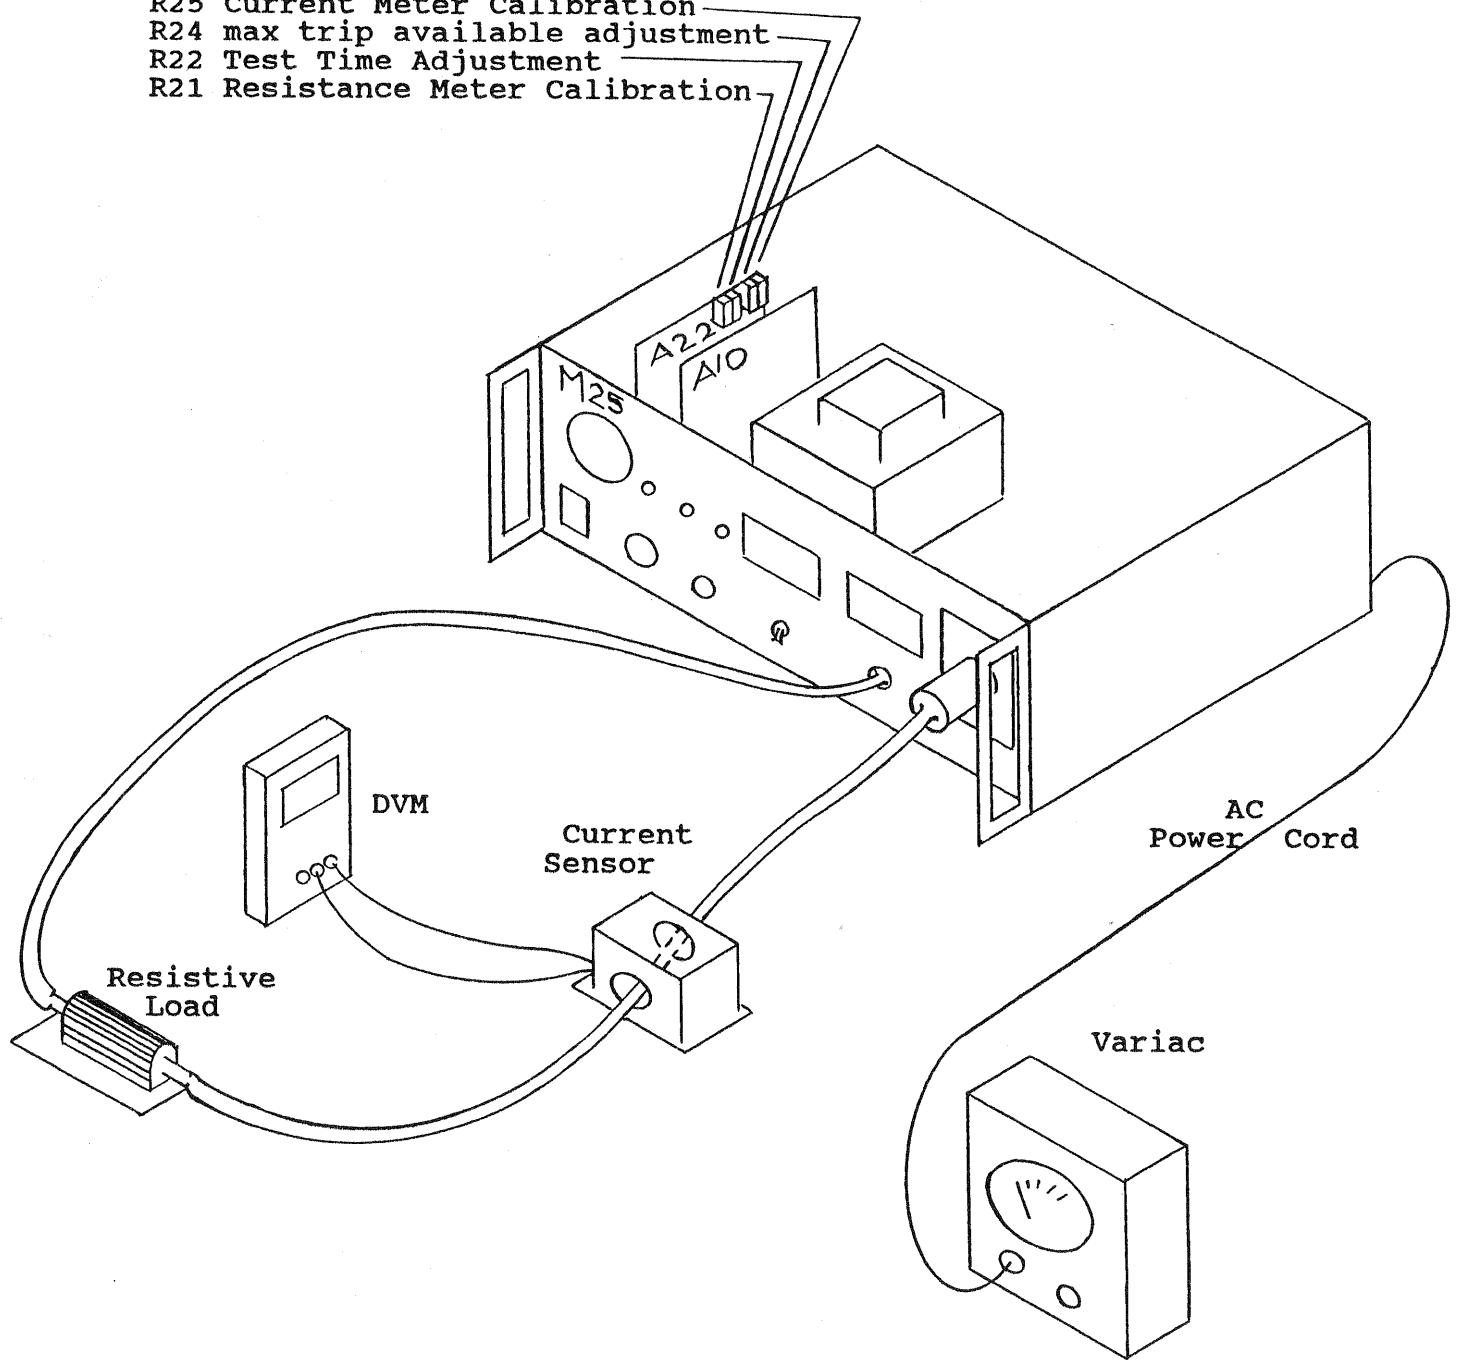

4-9. Fail Pots Calibration

Turn the OHM TRIP potentiometer on the Rear Panel fully CW (clockwise). With no load connected to the Ground Continuity Tester output, push the START button. The resistance meter should deflect to F.S. (full scale) and a failure mode produced; i.e., constant alarm sound and FAIL light on. Push RESET.

Connect the calibration load to the Ground Continuity Tester output as described in Section 4-6. Push the START button. While the test light is ON, slowly turn the OHM TRIP pot CCW until a failure mode is produced. Push RESET.

Figure 4-1: Test Set-Up

R25 Current Meter Calibration
R24 max trip available adjustment
R22 Test Time Adjustment
R21 Resistance Meter Calibration

R24 on the A22 Control Logic PCB controls the **MAXIMUM OHM TRIP POINT**, which is the highest resistance level to which the Ohm Trip Pot on the Rear Panel can be set. It should be set before setting the Ohm Trip Point with the Ohm Trip Pot on the Rear Panel. When set at the factory, a load equivalent to the F.S., (usually a 0.15Ω resistor) is used as a calibrating load with the OHM TRIP pot fully CW. Then, when the START button is pushed, the resistance meter should deflect to F.S., and a failure mode be produced. If a failure mode is not produced when the meter is deflecting to F.S., then adjust R24 until it is. Then Push RESET and proceed with Resistance Calibration.

4-10. List of Adjustment Pots

- | | |
|-----------------------|-------------------------------|
| A) R25 on the A22 PCB | Current Meter Calibration |
| B) R24 on the A22 PCB | Maximum Resistance Trip Point |
| C) R22 on the A22 PCB | Test Time Adjustment |
| D) R21 on the A22 PCB | Resistance Meter Calibration |

4-11. Trouble Shooting

Below is a list of problems, probable causes, and remedies for fault location. It should assist the technician in isolating a fault location. This table does not tabulate all the possible symptoms; only those Customer Service has determined most likely to occur.

A) No AC Power

- 1) Check fuses F1 and F2.

Recommended Fuses:

| | | |
|------|--------|---------------|
| F1,2 | 115VAC | 3A Slow blow |
| F3 | 115VAC | .5A Slow blow |
| F1,2 | 230VAC | 2A Slow blow |
| F3 | 230VAC | .5A Slow blow |

- 2) Check for bad AC Power Switch (S1) or Line Filter.
- 3) Measure for line voltage between Pin 1 of the solid state relay, K3, and Neutral.

B) Ground Continuity Tester blows fuses

- 1) Check for correct fuses.
- 2) Check for shorted varistors on the A7 PCB.
- 3) Troubleshoot the A10 Power Supply PCB.

C) Ready Lamp does not work

- 1) Check for burnt out bulb.
- 2) Check for bad +5V.
- 3) Check the driver on the A22 PCB.

D) No High Current Output

- 1) Check for bad start switch.
- 2) Check wiring harness for frayed wiring.
- 3) Check the solid state Relay, K3, and the triggering signal from the A22 PCB, pin 11.

E) No High Current with Failure Indication

- 1) Check OHM TRIP pot position. (see Section 4-9)
- 2) Check Load connection between the 25 amp output and the HV Return.
- 3) Check relays closure before the High Current Generation

Section 5

OPTIONS

5-1. Remote Control; Options 01 and 19

The Ground Continuity Tester has remote control capability when one of the Remote Options is used. It would include another PCB, and the signals would come through a DB-25 connector on the rear panel.

Several versions of the Remote Option are available (see schematic 01208-XX or 01306-02 or 00980-XX:) first, either Option 01 Digital or Option 19 Analog and Digital; second, with/without Automatic Reset Option; and third, with/without Pass Signal. The A8 Remote Control PCB is configured differently for the various combinations available.

5-1.1. A8 Remote Control P. C. Board Functions

The digital functions concern the status of the instrument and are available with Option 01. There are three inputs: *START*, *RESET*, and *SELECT A*. There are three outputs: *READY*, *TEST*, and *FAIL*. These signals are TTL compatible and optically isolated.

The analog functions provide buffering and adjustable gain for the resistance and current signals. The resistance buffer gain is adjusted to get 10VDC out of U11-10 (U11, pin 10) on the A8 PCB for a load of 0.1Ω .

The Automatic Reset Option makes the *FAIL* signal short in duration, and generates a *RESET* pulse after a failure is latched in the A22 Control Logic PCB. At the end of the Fail pulse, the system is completely Reset if no restart is attempted.

5-1.2. A8 Remote Control P. C. Board Theory

The *START* input starts a test cycle during the low to high transition. It has to remain high for about 15ms minimum.

RESET resets all Ground Continuity Tester operations when a high level is held.

TEST is a low level output when a test is in progress.

FAILURE is output at low level whenever there is an abortive condition during a test.

SELECT A, when held low, selects the Gnd Test / Hipot Test selection, and when high, selects Gnd Test only.

REMOTE (or *REM* on older units) selects the remote analog monitoring capability when a high level input is held.

The input current requirements for the digital signals are:

High Level 40uA @ +5V

Low Level 1.6mA @ 0.4V

The output current capabilities for the digital signals are:

High Level 2.27mA @ +5V

Low Level 2.27mA max @ +5V

When U3 is driven, a *RESET* signal is produced at Edge-card connector Pin 5, either directly through C, D jumpers or through U1 when the Automatic Reset Option is installed.

When U2 is driven, a *START* signal exits Edge-card connector Pin 9. (U9 driving is used only for M100/500 Hipot Tester versions of the PCB).

When the *GROUND TEST* signal through Edge-card connector Pin 10 is low, U6 is activated, and a low level is available at Edge-card connector Pin L to the Remote Connector.

When *TEST*, from Edge-card connector Pin 11, is low, i.e., a Test in Progress, U7 is activated, and a low level is available from Edge-card connector Pin M to the Remote Connector.

When U8 is activated by the *FAIL* signal, either from Edge-card connector Pin 12 or Edge-card connector Pin B when the Automatic Reset Option is used, a low level is available from Edge-card connector Pin N to the Remote Connector.

The Remote Controller's 5V and GND are fed through Edge-card connector Pins K and 15 respectively. The rest of the DB-25 pin assignments for using the A8 PCB are shown below:

| <u>DB 25 Pin #</u> | <u>Signal Name</u> | <u>Analog/Digital</u> |
|--------------------|--------------------------|-----------------------|
| 1 | EXTGND (Digital Supply) | |
| 2 | RMON | A |
| 3 | IMON | A |
| 4 | GND (GT Chassis) | |
| 5 - 15 not used | | |
| 16 | EXTGND (Digital Supply) | |
| 17 | REM | D |
| 18 | RESET | D |
| 19 | START | D |
| 20 | EXT +5V (Digital Supply) | |
| 21 | -READY | D |
| 22 | -TEST | D |
| 23 | -FAILURE | D |
| 24 | | |
| 25 | SELECTA | D |

5-1.3. Analog Option

When the M488 is interfaced with the Ground Continuity Tester, the A8 Remote Control PCB uses U11 as a non-inverting buffer with adjustable gain. R26 is adjusted for getting 10VDC out of Edge-card connector Pin 10 for 0.1Ω resistance. The resistance monitoring signal comes from the A22 Control Logic PCB through Edge-card connector Pin 7. R24 is for adjusting I MON OUT to 10VDC when there is no load on the output. R25 is for adjusting R MON OUT to 10VDC when a 0.1Ω load is connected at the output.

5-1.4. Automatic Reset Option

Referring to the A8 PCB schematic, 00980-XX, while in the TEST mode, a FAIL produces a one shot negative pulse in U4. The falling edge produces a one shot pulse in U5 which drives the alarm through Edge-card connector Pin B with Q2, and resets the system through the Edge-card connector Pin 5 with U1. At the end of the pulse from U5, the system is RESET and the alarm turned off. U1 also resets the system when REMOTE RESET is produced. If this Option is not needed, A, B, C, and D jumpers are placed so that the FAIL signal drives the alarm as normal, and the reset from the remote goes directly to the RESET line.

5-2. Option 06, Rear Panel Lockout Cover

Option 06 is a lexan cover for the rear panel controls. It is installed by removing the top cover to add the standoff hardware to the rear panel.

5-3. Option 07, Extra HV receptacle on Rear Panel

This option provides the rear panel with another 4-pin High Voltage receptacle. It is installed at the factory.

5-4. Option 10, Audible Test Tone

When Option 10 Audible Test Tone is installed in a Ground Continuity Tester, the alarm will sound pulses at 3 to 6 beeps per second whenever a TEST is in progress. This feature is produced by an additional IC and other discreet components on the A22 Control Logic PCB. A timer in U12 generates a pulse train signal, and Q5 drives the signal through Edge-card connector Pin 1 when the Test Latch is set.

5-5. Option 15, Rack Mounting

To rack mount the instrument, use Option 15 A. The procedure for installing the Rack Mounting Kit on the Ground Continuity Tester is as follows:

- A) Remove Extrusion insert (2 each) from both sides of instrument
- B) Place L-Bracket (2) and secure to chassis with four machine screws furnished with Mounting Kit
- C) Check that the screws and brackets are firmly secure

5-6. Option 24, Blank Front Panel Start Switch and/or HV Recp Block

This option removes the start switch, the front panel High Voltage receptacle, or both. A blank plate is installed, instead.

Section 6

BILLS OF MATERIALS, SCHEMATICS, DIAGRAMS

Following are M25 Bills Of Materials for help in identifying typical Rod-L part numbers.

SYSTEM OBJECTIVE
to perform a Ground Continuity, then an AC Hipot test automatically through one high voltage receptacle and with one press of the start switch.

SYSTEM SELF CHECK

use the intertrace cable (P/N 0033-04) to connect the "interface" connectors at the rear of each unit to each other.

- ① Connect "Chassis Ground Sense" (BP2, the black banana jack) at rear of the Ground Continuity Tester to "Chassis Ground Sense" (BP2) at front of the Hipot Tester.
- ② Connect "Ground" (the metal banana jack) at rear of the Ground Continuity Tester to "Ground" (the metal banana jack) at rear of the Hipot Tester.
- ③ Connect the High Current Ground Cable (P/N 00436-04; giant banana plug at one end, battery clip at the other) to the "Chassis Ground Sense" at the front of the Ground Continuity Tester and to its metal chassis frame.

The function select switch of the Ground Continuity Tester should be in the "GND/HIPO" position.

- 6 Plug both units into a common-ground AC outlet. Turn power of the Ground Continuity Tester on first, then power on the Hipot Tester. Both ready lights should then come on.

- 7 Press the Ground Continuity Tester's start button. The test begins, and after the ground continuity test is completed, the Hipot Tester will start automatically.

Now the system is ready for use.

SYSTEM USE

Assuming units are calibrated to the desired trip points, remove ground cable connection to the Ground Continuity Tester and connect it to the metal chassis frame of the Device Under Test (DUT).

- 2 Plug the DUT into the high voltage receptacle of the Ground Continuity Tester.
- 3 Press the Ground Continuity Tester's start button to begin the test.
- 4 For individual machine difficulties, see the appropriate manual.

SYSTEM OBJECTIVE
To perform a Ground Continuity, then a DC Hipot test automatically through one high voltage receptacle and with one press of the start switch.

SYSTEM SELF CHECK
Use the 4-pin-HV-connector interface cable (P/N 00333-04) to connect the "Interface connector" at the rear of the Ground Continuity Tester to the "Gnd Tester" connector at the rear of the M100DC.

① Connect together the "chassis Ground Sense" (black banana jack) at rear of each unit using a jumper cable with a standard banana plug at each end.

② Connect "Ground" (the metal banana jack) at rear of the Ground Continuity Tester to "Ground" (the metal banana jack) at rear of the Hipot Tester.

③ Connect the High Current Ground Cable (P/N 00436-04; giant banana plug at one end, battery clip at the other) to the "Chassis Ground Sense" at the front of the Ground Continuity Tester and to it's metal chassis frame.

④ Connect the High Current Ground Cable (P/N 00436-04; giant banana plug at one end, battery clip at the other) to the "Chassis Ground Sense" at the front of the Ground Continuity Tester and to it's metal chassis frame.

⑤ The function select switch of the Ground Continuity Tester should be in the "GND/HIPO" position.

⑥ Plugging both units into a common-ground AC outlet. Turn power on the Ground Continuity Tester on first, then power on the Hipot Tester. Both ready lights should then come on. If the M100DC ready light is not on, press the reset button.

⑦ Press the DUT into the high voltage receptacle of the Ground Continuity Tester.

THIS GROUND MUST BE IN PLACE!

REAR VIEW

SYSTEM USE

Assuming units are calibrated to the desired trip points, remove ground cable connection to the Ground Continuity Tester and connect it to the metal chassis frame or the Device Under Test (DUT).

① Plug the DUT into the high voltage receptacle of the Ground Continuity Tester.

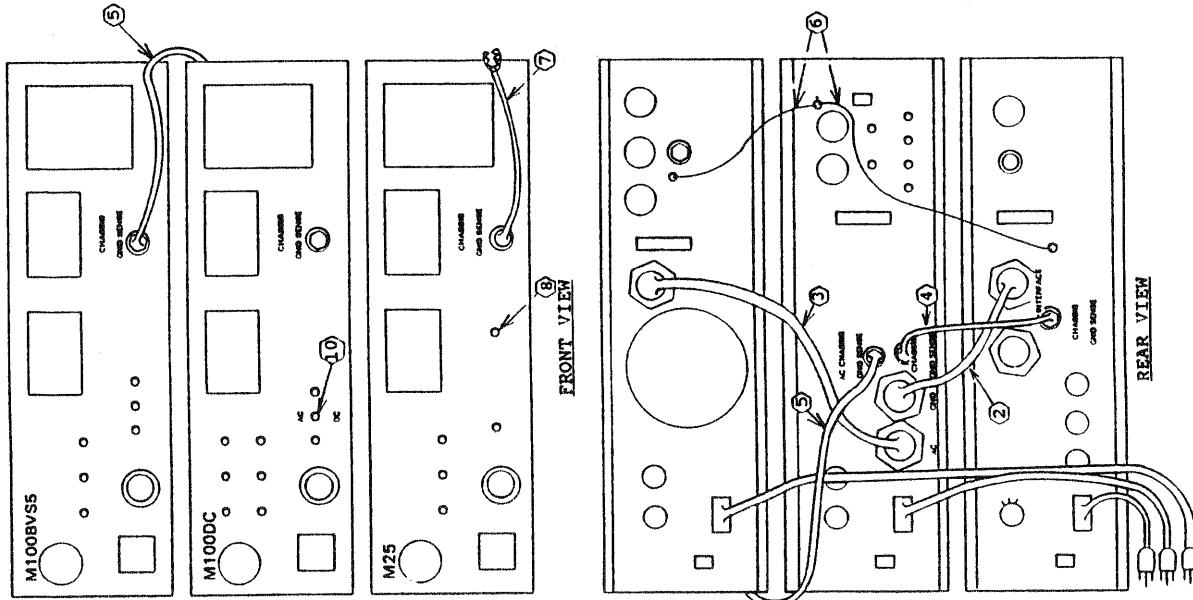

② Press the Ground Continuity Tester's start button to begin the test.

③ For individual machine difficulties, see the appropriate manual.

|------|------------------------|-----------|-----------|
| A | Initial release | 29 AG 86 | C Hollie |
| B | Redrawn, Corrected use | 11 May 95 | EDS |

SYSTEM OBJECTIVE

To perform Ground Continuity and AC or DC Hipot tests automatically through one high voltage receptacle.

SYSTEM SELF CHECK

Stack three units as shown.

- 1 Use a 4-pin-HV-connector interface cable (P/N 00333-04) to connect the "interface" connector at the rear of the Ground Continuity Tester to the "Grid Tester" connector at the rear of the M100DC.
- 2 Use a 4-pin-HV-connector interface cable (P/N 00333-04) to connect the "interface" connector at the rear of the AV or BV Hipot Tester to the "AC Hipot" connector at the rear of the M100DC.
- 3 Connect together the "Chassis Ground Sense" (black banana jack) at rear of the Ground Continuity Tester and rear of the M100DC using a jumper cable with a standard banana plug at each end.
- 4 Connect all the "Ground" (the black banana jack) front of the AV or BV Hipot Tester to "AC Chassis Gnd Sense" at the rear of the M100DC Hipot Tester by jumper cable with a standard banana plug at each end.
- 5 Connect the High Current Ground Cable (P/N 00436-04; giant banana plug at one end, battery clip at the other) to the "Chassis Ground Sense" at the front of the Ground Continuity Tester and to its metal chassis frame.
- 6 Connect the High Current Ground Cable (P/N 00436-04; giant banana plug at one end, battery clip at the other) to the "GND/HIPOT" position.
- 7 The function select switch of the Ground Continuity Tester should be in the "GND/HIPOT" position.
- 8 Plug the three units into an AC outlet. Turn power on the Ground Continuity Tester on first, then power on the Hipot Testers. The ready lights should then come on. Ready lights for the AV or BV and the M100DC correspond to the position of the "AC/DC" switch on the M100DC. Always press the "reset" button after switching from "AC" to "DC" to ensure the Ready light on the M100DC comes on.
- 9 To perform a DC test, put the AC/DC switch on the front of the M100DC in the "DC" position and press the START button of the Ground Continuity Tester. The ground continuity test begins, and when completed, the M100DC Hipot Tester will start automatically.
- 10 To perform an AC test, put the "AC/DC" switch on the front of the M100DC in the "AC" position and press the START button of the Ground Continuity Tester. The ground continuity test begins, and when completed, the AC Hipot Tester will start automatically.

Now the system is ready for use.

SYSTEM USE WITH THE DEVICE UNDER TEST

- 1 Assuming units are calibrated to the desired trip points, remove ground cable connection from the frame of the Ground Continuity Tester and connect it to the metal chassis frame of the Device Under Test (DUT).
- 2 Plug the DUT into the high voltage receptacle of the Ground Continuity Tester and follow procedures 10 above.
- 3 For individual machine difficulties, see the appropriate manual. WARNING!! High Voltage is present on both receptacles during the test at "AC" position.
