Advance Information High Frequency Clock Generator

The MC12439 is a general purpose synthesized clock source targeting applications that require both serial and parallel interfaces. Its internal VCO will operate over a range of frequencies from 400 to 800MHz. The differential PECL output can be configured to be the VCO frequency divided by 1, 2, 4, or 8. With the output configured to divide the VCO frequency by 1, and with a 16.66MHz external quartz crystal used to provide the reference frequency, the output frequency can be specified in 16.66MHz steps.

- 50 to 1000MHz Differential PECL Outputs
- ±25ps Peak-to-Peak Output Jitter
- Minimal Frequency Over-Shoot
- Synthesized Architecture
- Serial 3-Wire Interface
- Parallel Interface for Power-Up
- Quartz Crystal Interface
- 28-Lead PLCC Package
- Operates from 3.3V or 5.0V Power Supply

Functional Description

MC12439

HIGH FREQUENCY PLL

CLOCK GENERATOR

The internal oscillator uses the external quartz crystal as the basis of its frequency reference. The output of the reference oscillator is sent directly to the phase detector. With a 16.66MHz crystal, this provides a reference frequency of 16.66MHz. Although this data sheet illustrates functionality only for a 16MHz and 16.66MHz crystal, any crystal in the 10–25MHz range can be used. In addition to the crystal, an LVCMOS input can also be used as the PLL reference. The reference is selected via the XTAL_SEL input pin.

The VCO within the PLL operates over a range of 400 to 800MHz. Its output is scaled by a divider that is configured by either the serial or parallel interfaces. The output of this loop divider is also applied to the phase detector.

The phase detector and loop filter attempt to force the VCO output frequency to be M times the reference frequency by adjusting the VCO control voltage. Note that for some values of M (either too high or too low) the PLL will not achieve loop lock.

The output of the VCO is also passed through an output divider before being sent to the PECL output driver. This output divider is configured through either the serial or the parallel interfaces, and can provide one of four division ratios (1, 2, 4, or 8). This divider extends performance of the part while providing a 50% duty cycle.

The output driver is driven differentially from the output divider, and is capable of driving a pair of transmission lines terminated in 50Ω to V_{CC} - 2.0.

The configuration logic has two sections: serial and parallel. The parallel interface uses the values at the M[6:0] and N[1:0] inputs to configure the internal counters. Normally, on system reset, the P_LOAD input is held LOW until sometime after power becomes valid. On the LOW-to-HIGH transition of P_LOAD , the parallel inputs are captured. The parallel interface has priority over the serial interface. Internal pullup resistors are provided on the M[6:0] and N[1:0] inputs to reduce component count in the application of the chip.

The serial interface centers on a twelve bit shift register. The shift register shifts once per rising edge of the S_CLOCK input. The serial input S_DATA must meet setup and hold timing as specified in the AC Characteristics section of this document. The configuration latches will capture the value of the shift register on the HIGH-to-LOW edge of the S_LOAD input. See the programming section for more information.

The TEST output reflects various internal node values, and is controlled by the T[2:0] bits in the serial data stream. See the programming section for more information.

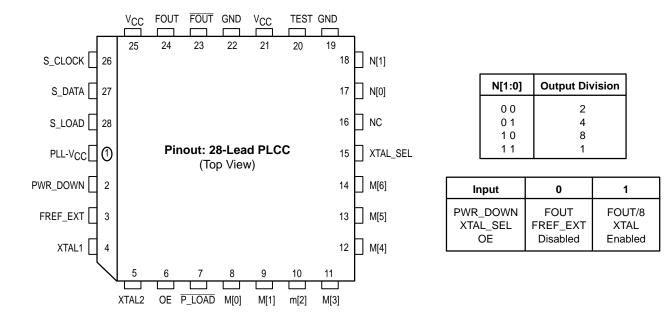

The PWR_DOWN pin, when asserted, will synchronously divide the FOUT by 8. The power down sequence is clocked by the PLL reference clock, thereby causing the frequency reduction to happen relatively slowly. Upon de-assertion of the PWR_DOWN pin, the FOUT input will slowly step back up to its programmed frequency.

PIN DESCRIPTIONS

Pin Name	Туре	Function			
Inputs	•				
XTAL1, XTAL2	—	These pins form an oscillator when connected to an external series-resonant crystal.			
S_LOAD	Int. Pulldown	This pin loads the configuration latches with the contents of the shift registers. The latches will be transparent when this signal is HIGH, thus the data must be stable on the HIGH-to-LOW transition of S_LOAD for proper operation.			
S_DATA	Int. Pulldown	This pin acts as the data input to the serial configuration shift registers.			
S_CLOCK	Int. Pulldown	This pin serves to clock the serial configuration shift registers. Data from S_DATA is sampled on the rising edge.			
P_LOAD	Int. Pullup	This pin loads the configuration latches with the contents of the parallel inputs .The latches will be transparent when this signal is LOW, thus the parallel data must be stable on the LOW-to-HIGH transition of \overline{P} _LOAD for proper operation.			
M[6:0]	Int. Pullup	These pins are used to configure the PLL loop divider. They are sampled on the LOW-to-HIGH transition of \overline{P} _LOAD. M[8] is the MSB, M[0] is the LSB.			
N[1:0]	Int. Pullup	These pins are used to configure the output divider modulus. They are sampled on the LOW-to-HIGH transition of \overline{P} _LOAD.			
OE	Int. Pullup	Active HIGH Output Enable.			
Outputs					
Fout, Fout	—	These differential positive-referenced ECL signals (PECL) are the output of the synthesizer.			
TEST	—	The function of this output is determined by the serial configuration bits T[2:0].			
Power					
VCC	—	This is the positive supply for the chip, and is connected to +3.3V or 5.0V ($V_{CC} = PLL_V_{CC}$).			
PLL_V _{CC}	—	This is the positive supply for the PLL, and should be as noise-free as possible for low-jitter operation. This supply is connected to +3.3V or 5.0V ($V_{CC} = PLL_{VCC}$).			
GND	—	These pins are the negative supply for the chip and are normally all connected to ground.			
Other					
PWR_DOWN	Int. Pulldown	LVCMOS input that forces the FOUT output to synchronously reduce its frequency by a factor of 8.			
FREF_EXT	Int. Pulldown	LVCMOS input which can be used as the PLL reference frequency.			
XTAL_SEL	Int. Pullup	LVCMOS input that selects between the XTAL and FREF_EXT PLL reference inputs. A HIGH selects the XTAL input.			

PROGRAMMING INTERFACE

Programming the device amounts to properly configuring the internal dividers to produce the desired frequency at the outputs. The output frequency can by represented by this formula:

 $FOUT = F_{XTAL} \times M \div N$ (1)

Where F_{XTAL} is the crystal frequency, M is the loop divider modulus, and N is the output divider modulus. Note that it is possible to select values of M such that the PLL is unable to achieve loop lock. To avoid this, always make sure that M is selected to be $25 \le M \le 50$ for a 16MHz input reference.

For input references other than 16MHz, the valid M values can be calculated from the valid VCO range of 400–800MHz.

Assuming that a 16MHz reference frequency is used the above equation reduces to:

FOUT = $16 \times M \div N$

Substituting the four values for N (1, 2, 4, 8) yields:

FOUT = 16M, FOUT = 8M, FOUT = 4M and FOUT = 2M for 25 < M < 50

The user can identify the proper M and N values for the desired frequency from the above equations. The four output frequency ranges established by N are 400–800MHz, 200–400MHz, 100–200MHz and 50–100MHz respectively. From these ranges the user will establish the value of N required, then the value of M can be calculated based on the appropriate equation above. For example if an output frequency of 384MHz was desired the following steps would be taken to identify the appropriate M and N values. 384MHz falls within the frequency range set by an N value of 2 so N [1:0] = 00. For N = 2 FOUT = 8M and M = FOUT \div 8. Therefore M = 384 \div 8 = 48, so M[8:0] = 0110000.

For input reference frequencies other than 16MHz the set of appropriate equations can be deduced from equation 1. For computer applications another useful frequency base would be 16.666MHz. From this reference one can generate a family of output frequencies at multiples of the 33.333MHz PCI clock. As an example to generate a 533.333MHz clock from a 16.666MHz reference the following M and N values would be used:

FOUT = 16.666 x M ÷ N Let N = 1, M = 533.333 ÷ 16.666 = 32

The value for M falls within the constraints set for PLL stability $(400 \div 16.666 \le M \le 800 \div 16.666; 24 \le M \le 48)$, therefore N[1:0] = 11 and M[6:0] = 0100000. If the value for M fell outside of the valid range a different N value would be selected to try to move M in the appropriate direction.

The M and N counters can be loaded either through a parallel or serial interface. The parallel interface is controlled via the $\overline{P_LOAD}$ signal such that a LOW to HIGH transition will latch the information present on the M[6:0] and N[1:0] inputs into the M and N counters. When the P LOAD signal is LOW the input latches will be transparent and any changes on the M[6:0] and N[1:0] inputs will affect the FOUT output pair. To use the serial port the S_CLOCK signal samples the information on the S_DATA line and loads it into a 12 bit shift register. Note that the P_LOAD signal must be HIGH for the serial load operation to function. The Test register is loaded with the first three bits, the N register with the next two and the M register with the final eight bits of the data streeam on the S_DATA input. For each register the most significant bit is loaded first (T2, N1 and M6). A pulse on the S_LOAD pin after the shift register is fully loaded will transfer the divide values into the counters. The HIGH to LOW transition on the S LOAD input will latch the new divide values into the counters. NO TAG illustrates the timing diagram for both a parallel and a serial load of the MC12439 synthesizer.

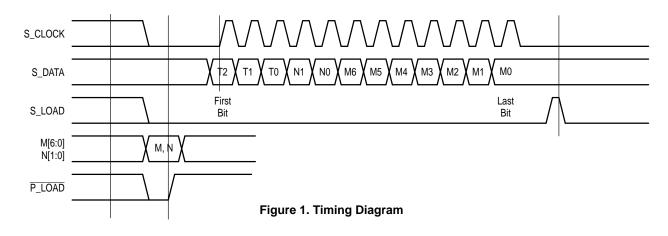

M[6:0] and N[1:0] are normally specified once at power-up through the parallel interface, and then possibly again through the serial interface. This approach allows the application to come up at one frequency and then change or fine-tune the clock as the ability to control the serial interface becomes available.

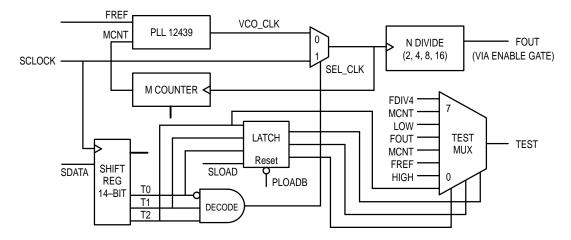

The TEST output provides visibility for one of the several internal nodes as determined by the T[2:0] bits in the serial

configuration stream. It is not configurable through the parallel interface. Although it is possible to select the node that represents FOUT, the CMOS output may not be able to toggle fast enough for some of the higher output frequencies. The T2, T1 and T0 control bits are preset to '000' when P_LOAD is LOW so that the PECL FOUT outputs are as jitter-free as possible. Any active signal on the TEST output pin will have detrimental affects on the jitter of the PECL output pair. In normal operations, jitter specifications are only guaranteed if the TEST output is static. The serial configuration port can be used to select one of the alternate functions for this pin.

Most of the signals available on the TEST output pin are useful only for performance verification of the MC12439 itself. However the PLL bypass mode may be of interest at the board level for functional debug. When T[2:0] is set to 110 the MC12439 is placed in PLL bypass mode. In this mode the S_CLOCK input is fed directly into the M and N dividers. The N divider drives the FOUT differential pair and the M counter drives the TEST output pin. In this mode the S CLOCK input could be used for low speed board level functional test or debug. Bypassing the PLL and driving FOUT directly gives the user more control on the test clocks sent through the clock tree. NO TAG shows the functional setup of the PLL bypass mode. Because the S_CLOCK is a CMOS level the input frequency is limited to 250MHz or less. This means the fastest the FOUT pin can be toggled via the S_CLOCK is 250MHz as the minimum divide ratio of the N counter is 1. Note that the M counter output on the TEST output will not be a 50% duty cycle due to the way the divider is implemented.

T2	T1	Т0	TEST (Pin 19)
0	0	0	SHIFT REGISTER OUT
0	0	1	HIGH
0	1	0	FREF
0	1	1	M COUNTER OUT
1	0	0	FOUT
1	0	1	LOW
1	1	0	PLL BYPASS
1	1	1	FOUT/4

- T2=T1=1, T0=0: Test Mode
- SCLOCK is selected, MCNT is on TEST output, SCLOCK DIVIDE BY N is on FOUT pin

PLOADB acts as reset for test pin latch. When latch reset T2 data is shifted out TEST pin.

APPLICATIONS INFORMATION

Using the On–Board Crystal Oscillator

The MC12439 features a fully integrated on-board crystal oscillator to minimize system implementation costs. The oscillator is a series resonant, multivibrator type design as opposed to the more common parallel resonant oscillator design. The series resonant design provides better stability and eliminates the need for large on chip capacitors. The oscillator is totally self contained so that the only external component required is the crystal. As the oscillator is somewhat sensitive to loading on its inputs the user is advised to mount the crystal as close to the MC12439 as possible to avoid any board level parasitics. To facilitate co-location surface mount crystals are recommended, but not required. Because the series resonant design is affected by capacitive loading on the xtal terminals loading variation introduced by crystals from different vendors could be a potential issue. For crystals with a higher shunt capacitance it may be required to place a resistor across the terminals to suppress the third harmonic. Although typically not required it is a good idea to layout the PCB with the provision of adding this external resistor. The resistor value will typically be between 500 and 1KQ.

The oscillator circuit is a series resonant circuit and thus for optimum performance a series resonant crystal should be used. Unfortunately most crystals are characterized in a parallel resonant mode. Fortunately there is no physical difference between a series resonant and a parallel resonant crystal. The difference is purely in the way the devices are characterized. As a result a parallel resonant crystal can be used with the MC12439 with only a minor error in the desired frequency. A parallel resonant mode crystal used in a series resonant circuit will exhibit a frequency of oscillation a few hundred ppm lower than specified, a few hundred ppm translates to kHz inaccuracies. In a general computer application this level of inaccuracy is immaterial. Table 1 below specifies the performance requirements of the crystals to be used with the MC12439.

Table 1. Crystal Specifications

Parameter	Value			
Crystal Cut	Fundamental AT Cut			
Resonance	Series Resonance*			
Frequency Tolerance	±75ppm at 25°C			
Frequency/Temperature Stability	±150pm 0 to 70°C			
Operating Range	0 to 70°C			
Shunt Capacitance	5–7pF			
Equivalent Series Resistance (ESR)	50 to 80Ω			
Correlation Drive Level	100µW			
Aging	5ppm/Yr (First 3 Years)			

See accompanying text for series versus parallel resonant discussion.

Power Supply Filtering

The MC12439 is a mixed analog/digital product and as such it exhibits some sensitivities that would not necessarily be seen on a fully digital product. Analog circuitry is naturally susceptible to random noise, especially if this noise is seen on the power supply pins. The MC12439 provides separate power supplies for the digital ciruitry (V_{CC}) and the internal PLL (PLL_VCC) of the device. The purpose of this design technique is to try and isolate the high switching noise digital outputs from the relatively sensitive internal analog phase–locked loop. In a controlled environment such as an

evaluation board this level of isolation is sufficient. However, in a digital system environment where it is more difficult to minimize noise on the power supplies a second level of isolation may be required. The simplest form of isolation is a power supply filter on the PLL_VCC pin for the MC12439.

Figure 3 illustrates a typical power supply filter scheme. The MC12439 is most susceptible to noise with spectral content in the 1KHz to 1MHz range. Therefore the filter should be designed to target this range. The key parameter that needs to be met in the final filter design is the DC voltage drop that will be seen between the VCC supply and the PLL_VCC pin of the MC12439. From the data sheet the IPLL VCC current (the current sourced through the PLL_VCC pin) is typically 15mA (20mA maximum), assuming that a minimum of 3.0V must be maintained on the PLL_VCC pin very little DC voltage drop can be tolerated when a 3.3V VCC supply is used. The resistor shown in Figure 3 must have a resistance of $10-15\Omega$ to meet the voltage drop criteria. The RC filter pictured will provide a broadband filter with approximately 100:1 attenuation for noise whose spectral content is above 20KHz. As the noise frequency crosses the series resonant point of an individual capacitor it's overall impedance begins to look inductive and thus increases with increasing frequency. The parallel capacitor combination shown ensures that a low impedance path to ground exists for frequencies well above the bandwidth of the PLL.

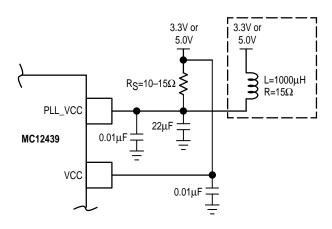

Figure 3. Power Supply Filter

A higher level of attenuation can be acheived by replacing the resistor with an appropriate valued inductor. Figure 3 shows a 1000 μ H choke, this value choke will show a significant impedance at 10KHz frequencies and above. Because of the current draw and the voltage that must be maintained on the PLL_VCC pin a low DC resistance inductor is required (less than 15 Ω). Generally the resistor/capacitor filter will be cheaper, easier to implement and provide an adequate level of supply filtering.

The MC12439 provides sub–nanosecond output edge rates and thus a good power supply bypassing scheme is a must. Figure 4 shows a representaive board layout for the MC12439. There exists many different potential board layouts and the one pictured is but one. The important aspect of the layout in Figure 4 is the low impedance connections between VCC and GND for the bypass capacitors. Combining good quality general purpose chip capacitors with good PCB layout techniques will produce effective capacitor resonances at frequencies adequate to supply the instantaneous switching current for the 12439 outputs. It is imperative that low inductance chip capacitors are used; it is equally important that the board layout does not introduce back all of the inductance saved by using the leadless capacitors. Thin interconnect traces between the capacitor and the power plane should be avoided and multiple large vias should be used to tie the capacitors to the buried power planes. Fat interconnect and large vias will help to minimize layout induced inductance and thus maximize the series resonant point of the bypass capacitors.

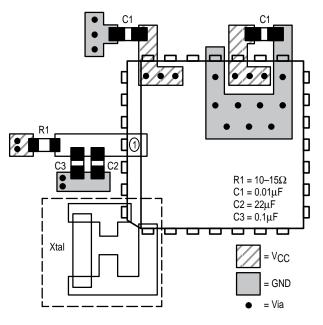

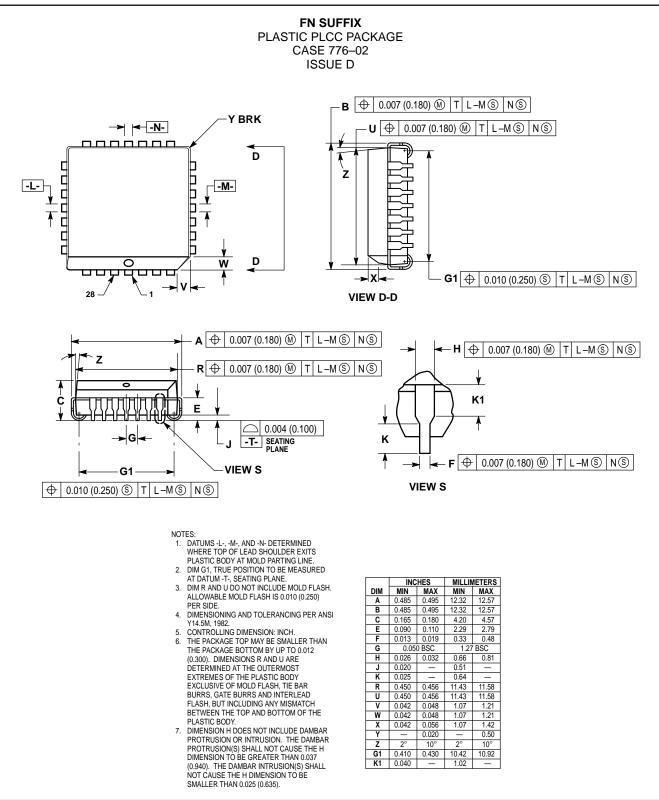

Figure 4. PCB Board Layout for MC12439

Note the dotted lines circling the crystal oscillator connection to the device. The oscillator is a series resonant circuit and the voltage amplitude across the crystal is relatively small. It is imperative that no actively switching signals cross under the crystal as crosstalk energy coupled to these lines could significantly impact the jitter of the device. Special attention should be paid to the layout of the crystal to ensure a stable, jitter free interface between the crystal and the on-board oscillator. Note the provisions for placing a resistor across the crystal oscillator terminals as discussed in the crystal oscillator section of this data sheet.

Although the MC12439 has several design features to minimize the susceptibility to power supply noise (isolated power and grounds and fully differential PLL) there still may be applications in which overall performance is being degraded due to system power supply noise. The power supply filter and bypass schemes discussed in this section should be adequate to eliminate power supply noise related problems in most designs.
