

**$2 \times 24\text{ W}$  BTL or  $4 \times 12\text{ W}$  single-ended  
car radio power amplifier**
**TDA8564Q****FEATURES**

- Requires very few external components
- High output power
- Flexibility in use - Quad single-ended or stereo BTL
- Low output offset voltage
- Fixed gain
- Diagnostic facility (distortion, short-circuit and temperature detection)
- Good ripple rejection
- Mode select switch (operating, mute and standby)
- Load dump protection
- AC and DC short-circuit safe to ground and to  $V_P$
- Low power dissipation in any short-circuit condition
- Thermally protected
- Reverse polarity safe

- Electrostatic discharge protection
- No switch-on/switch-off plop
- Flexible leads
- Low thermal resistance
- Identical inputs (inverting and non-inverting).

**GENERAL DESCRIPTION**

The TDA8564Q is an integrated class-B output amplifier in a 17-lead DIL-bent-SIL power package. It contains  $4 \times 12\text{ W}$  single-ended or  $2 \times 24\text{ W}$  bridge amplifiers.

**APPLICATIONS**

- The device is primarily developed for car radio applications.

**QUICK REFERENCE DATA**

SYMBOL	PARAMETER	CONDITIONS	MIN.	TYP.	MAX.	UNIT
$V_P$	operating supply voltage		6.0	14.4	18.0	V
$I_{ORM}$	repetitive peak output current		—	—	4	A

INV3	15	inverting input 3
$V_{DIAG}$	16	diagnostic output
-INV4	17	non-inverting input 4

**FUNCTIONAL DESCRIPTION**

The TDA8564Q contains four identical amplifiers which can be used for single-ended or bridge applications. The gain of each amplifier is fixed at 40 dB (46 dB in BTL). Special features of the device are as follows.

**Mode select switch (pin 14)**

- Low standby current (<100  $\mu$ A)
- Low switching current (low cost supply switch)
- Mute facility.

To avoid switch-on plops, it is advised to keep the amplifier in the mute mode during  $\geq 100$  ms (charging of the input capacitors at pins 1, 3, 15 and 17).

This can be achieved by:

- Microcontroller control
- External timing circuit (see Fig.3).

The circuit in Fig.3 slowly ramps up the voltage at the mode select switch pin when switching on and results in fast muting when switching off.

In the event of fast switching at mode select pin it is advised to increase the  $\frac{1}{2}V_P$  decoupling capacitor (pin 4) to 150  $\mu$ F to avoid switch plops.

Fig.3 Mode select switch circuitry.

### **Diagnostic output (pin 16)**

#### DYNAMIC DISTORTION DETECTOR (DDD)

At the onset of clipping of one or more output stages, the dynamic distortion detector becomes active and pin 16 goes LOW. This information can be used to drive a sound processor or DC volume control to attenuate the input signal and thus limit the distortion. The output level of pin 16 is independent of the number of channels that are clipping (see Figs 4 and 5).

#### SHORT-CIRCUIT PROTECTION

When a short-circuit occurs at one or more outputs to ground or to the supply voltage, the output stages are switched off until the short-circuit is removed and the device is switched on again, with a delay of approximately 20 ms after removal of the short-circuit. During this short-circuit condition, pin 16 is continuously LOW.

When a short-circuit across the load of one or more channels occurs the output stages are switched off during

approximately 20 ms. After that time it is checked during approximately 50  $\mu\text{s}$  to see whether the short-circuit is still present. Due to this duty cycle of 50  $\mu\text{s}/20\text{ ms}$  the average current consumption during this short-circuit condition is very low (approximately 40 mA).

During this short-circuit condition, pin 16 is LOW for 20 ms and HIGH for 50  $\mu\text{s}$  (see Fig.6).

The power dissipation in any short-circuit condition is very low.

#### TEMPERATURE DETECTION

When the virtual junction temperature  $T_{vj}$  reaches 150 °C, pin 16 will be active LOW.

#### OPEN-COLLECTOR OUTPUT

Pin 16 is an open-collector output, which allows pin 16 of more devices being tied together.
