Preliminary specification

Dual Dolby* B-type noise reduction circuit for playback applications

TEA0675

FEATURES	This device also detects pauses of music in the Automatic
Dual noise reduction (NR) channels	Music Search (AMS) scan mode, for applications with an intelligent controlled tape driver, or AMS-latch mode, for
 Head pre-amplifiers 	applications with a simple controlled tape driver. For both
Reverse head switching	modes, the delay time can be fixed externally by a resistor.
Automatic Music Search (AMS)	The device operates with power supplies in the range of 7.6 to 12 V, output overload level increasing with increase
Music scan	in supply voltage.
Equalization with electronically switched time constants	Current drain varies with the following variables:
 Dolby reference level = 387.5 mV 	supply voltage
• 24 pins	noise reduction on/off

• Improved EMC behaviour.

GENERAL DESCRIPTION

The TEA0675 is a bipolar integrated circuit that provides two channels of Dolby B noise reduction for playback applications in car radios. It includes head and equalization amplifiers with electronically switchable time constants. Furthermore it includes electronically switchable inputs for tape drivers with reverse heads. AMS on/off.

Because of this current drain variation it is advisable to use a regulated power supply or a supply with a long time constant.

TEA0675

FUNCTIONAL DESCRIPTION

Noise Reduction (NR) is enabled when pin HPB is open-circuit and disabled when connected to GND via an 1.5 k Ω resistor.

Dolby B noise reduction only operates correctly if 0 dB Dolby level is adjusted at 387.5 mV.

Automatic Music Search (AMS) scan mode is enabled when pin HPA is connected to V_{CC} via an 1.5 k Ω resistor and disabled when pin HPA is open-circuit. Switching AMS on, internally NR is switched OFF simultaneously (see Figs 5 and 6 for principle timing in AMS-scan mode).

AMS-latch mode is enabled when pin HPA is connected to GND via an 1.5 k Ω resistor and disabled when pin HPA is open-circuit. Switching AMS on, NR is switched off internally. In this mode the device detects a pause level signal, when a music level signal has appeared first (see Figs 7 and 8 for principle timing). Furthermore a longer rise time constant is supplied for suppressing the detection of plops on tape. The output signal at pin AMSEQ in this mode may be applied to drive a tape driver logic circuit. Equalization time constant switching (70 μ s or 120 μ s) is achieved when pin AMSEQ is connected to GND via an 18 k Ω resistor (120 μ s), or left open-circuit (70 μ s). This does not affect the AMS output signal during AMS mode (see Fig.1).

Head switching is achieved when pin HS is connected (input IN2 active) to GND via a 27 k Ω resistor, or left open-circuit (input IN1 active). The 10 μ F capacitor at pin HS sets the time constants for smooth switching.

In AMS mode the signals of both channels are rectified and then added. This means, even if one channel signal appears inverted to the other channel, the normal AMS function is ensured. Pins HPB and HPA perform the function of a logic input for AMS, respectively NR mode switching in both channels and provide the frequency dependent feedback of the control chain amplifier in the corresponding channel. Thus it is important that no voltage is applied to pins HPB and HPA during NR on/AMS off mode, otherwise this will cause irregular NR characteristics.

LIMITING VALUES

In accordance with the Absolute Maximum Rating System (IEC 134).

SYMBOL	PARAMETER	CONDITIONS	MIN.	MAX.	UNIT

Notes

- 1. In AMS off mode, pin AMSEQ is HIGH level, the equalization time constant will be switched by pulling approximately 200 μ A out of pin AMSEQ. This means for the device connected to pin AMSEQ, a restriction of input current at HIGH level less than 200 μ A during AMS off; otherwise the selection of the equalization time constant is disabled and fixed at 120 μ s. If the connected devices consume more than 200 μ A, this input has to be disconnected in AMS off mode. (To ensure switching, the currents for the different switched modes are specified with a tolerance of ±50 μ A in Chapter "Characteristics".) For an application with a fixed EQ time constant of 120 μ s the equalizing network may be applied completely external. Change 8.2 k Ω resistor to 14 k Ω the internal resistor R_{EQ} = 5.8 k Ω is short-circuited by fixing the EQ switch input at the 70 μ s position (I_{EQ70}).
- 2. The high speed of the tape (FF, REW) at the tape head during AMS mode causes a transformation of level and frequency of the originally recorded signal. It means a boost of signal level of approximately 10 dB and more for recorded frequencies from 500 Hz up to 4 kHz. So the threshold level of –22 dB corresponds to signal levels in Play Back (PB) mode of approximately –32 dB. The AMS inputs for each channel are pin SCA and pin SCB. As the frequency spectrum is transformed by a factor of approximately 10 to 30 due to the higher tape speed in FF, REW, the high-pass filter (4.7 nF/24 kΩ) removes the effect of offset voltages but does not affect the music search function.

In the application circuit (Fig.1) the frequency response of the system between tape heads input, e.g. pins INA2 and INB2, to the AMS input pins SCA and SCB is constant over the whole frequency range (see Fig.3).

3. To activate the inputs IN1, pin HS might be left open-circuit. In this event the DC level at pin HS is $0.775V_{CC}$.

TEA0675

Table 1 Blank delay time set by resistor Rt at pin TD

RESISTOR VALUE Rt (kΩ)	DELAY TIME t _d TYP. (ms)	TOLERANCE (%)
68	23	20
150	42	15
180	48	15
220	56	15
270	65	10
330	76	10
470	98	10
560	112	10
680	126	10
820	142	10
1000	160	10

General note

It is recommended to switch off V_{CC} with a gradient of 400 V/s at maximum to avoid plops on tape in the event of contact between tape and tape head while switching off.

TEA0675

Dual Dolby* B-type noise reduction circuit for playback applications

Short description 'music search'

A system for 'music search' mainly consists of a level and a time detection (see Fig.4). For adapting and decoupling the input signal will be amplified (A), then rectified (B) and smoothed with a time constant (C). So the voltage at (C) corresponds to the signal level and will be compared to the predefined pause level at the first comparator (D), the level detector. If the signal level becomes smaller than the pause level, the level detector changes its output signal. Due to the output level of the level detector the capacitor of the second time constant (E) will be charged, respectively discharged. If the pause level of the input signal remains for a certain time, the voltage at the capacitor reaches a certain value, which corresponds to an equivalent time value. The voltage at the capacitor will be compared to a predefined time-equivalent voltage by the second comparator (F), the time detector. If the pause level of the input signal remains for this predefined time, the time detector changes its output level for 'pause found' status.

aut descriptions (monsis as ande)

TEA0675

Description of the principle timing diagram for AMS-scan mode without initial input signal (see Fig.5)

By activating AMS-scan mode, the AMS output level directly indicates whether the input level corresponds to a pause level ($V_{AMSEQ} = LOW$) or not ($V_{AMSEQ} = HIGH$). At t₀ the AMS-scan mode is activated. Without a signal at V_{in} , the following initial procedure runs until the AMS output changes to LOW level: due to no signal at V_{in} the voltage at the level detector input V_{I} (pin 3, CONTRA) remains below the level threshold and the second time constant will be discharged (time detector input V_{t}). When V_{t} passes the time threshold level, the time detector output changes to LOW level. Now the initial procedure is completed.

If a signal burst appears at t_3 , the level detector input voltage rises immediately and causes its output to charge the second time constant, which supplies the input voltage V_t for the time detector. When V_t passes the upper

threshold level after the rise time t_r (at t_4), the AMS output changes to HIGH. If the signal burst ends at t_5 the level detector input V₁ falls to its LOW level. When passing the level threshold at t_6 , the discharging of the second time constant begins. Now the circuit measures the delay time t_d , which is externally fixed by a resistor and defines the length of a pause to be detected. If no signal appears at V_{in} within the time interval t_d , the time detector output switches the AMS output to LOW level at t_7 .

If a plop noise pulse appears at V_{in} (t₈) with a pulse width less than the rise time $t_r > t_b$, the plop noise will not be detected as music. The AMS output remains LOW.

Similarly the system handles 'no music pulses' t_p: when music appears at t_{11} with a small interruption at t_{13} , this interruption will not affect the AMS output for $t_p < t_d$.

TEA0675

Description of the principle timing diagram for AMS-scan mode with initial input signal (see Fig.6)

At t_0 the AMS-scan mode is activated. With an input signal at V_{in} , the following initial procedure runs until the circuit gets a steady state status.

Due to the signal at V_{in} the voltage at the level detector input V_{I} (pin 3, CONTRA) slides to a value which is defined by a limiter. This voltage causes the level detector output charging the second time constant (time detector input V_{t}) to its maximum voltage level at t_1 . Now the initial procedure is completed.

The following behaviour does not differ from the description in Section "Description of the principle timing diagram for AMS-scan mode without initial input signal (see Fig.5)".

TEA0675

Description of the principle timing diagram for AMS-latch mode without initial input signal (see Fig.7)

This is similar to the description of the principle timing diagram from AMS-scan mode. It only differs in its initial behaviour and its rise time t_r . (Please notice that the different t_r does not occur in the principle timing diagrams for latch and scan mode).

Running in AMS-latch mode, the circuit may be simply applied to drive a stop solenoid via a power FET. So the AMS output signal has not to be processed by a controller. Because there is no processor to make a decision whether there is a plop noise or not, for this mode the rise time t_r is extended to approximately 150 ms.

By activating AMS-latch mode the AMS output will not change to LOW level at t_2 if there is no initial signal at V_{in} .

A latch forces the AMS output to be HIGH until a signal appears at V_{in} (t₄). After t₄ the latch will not affect the output any more until AMS-latch mode is started again. The existence of the latch appears necessary if the AMS output for example drives a stop solenoid via a power FET. The LOW output level will cause a drive of the stop solenoid. This would happen after a maximum time of t_d occurred without any input signal. If there is no music on tape for a long time (e.g. at tape end), the AMS mode would be activated repeatedly as long as there is no signal at V_{in}. Thus the circuit waits until first music appears before detecting the pauses.

TEA0675

Description of the principle timing diagram for AMS-latch mode with initial input signal (see Fig.8)

This is similar to the description in Section "Description of the principle timing diagram for AMS-scan mode with initial input signal (see Fig.6)". It only differs in its rise time t_r and a release of its internal latch when voltage V_t passes the upper threshold between t_0 and t_1 . Now the initial procedure is completed.

The following behaviour does not differ from the description in Section "Description of the principle timing diagram for AMS-latch mode without initial input signal (see Fig.7)".

SOLDERING

Introduction

There is no soldering method that is ideal for all IC packages. Wave soldering is often preferred when through-hole and surface mounted components are mixed on one printed-circuit board. However, wave soldering is not always suitable for surface mounted ICs, or for printed-circuits with high population densities. In these situations reflow soldering is often used.

This text gives a very brief insight to a complex technology. A more in-depth account of soldering ICs can be found in our *"IC Package Databook"* (order code 9398 652 90011).

SDIP

SOLDERING BY DIPPING OR BY WAVE

The maximum permissible temperature of the solder is 260 °C; solder at this temperature must not be in contact with the joint for more than 5 seconds. The total contact time of successive solder waves must not exceed 5 seconds.

The device may be mounted up to the seating plane, but the temperature of the plastic body must not exceed the specified maximum storage temperature ($T_{stg max}$). If the printed-circuit board has been pre-heated, forced cooling may be necessary immediately after soldering to keep the temperature within the permissible limit.

REPAIRING SOLDERED JOINTS

Apply a low voltage soldering iron (less than 24 V) to the lead(s) of the package, below the seating plane or not more than 2 mm above it. If the temperature of the soldering iron bit is less than $300 \,^{\circ}$ C it may remain in contact for up to 10 seconds. If the bit temperature is between 300 and 400 $^{\circ}$ C, contact may be up to 5 seconds.

SO

REFLOW SOLDERING

Reflow soldering techniques are suitable for all SO packages.

Reflow soldering requires solder paste (a suspension of fine solder particles, flux and binding agent) to be applied to the printed-circuit board by screen printing, stencilling or pressure-syringe dispensing before package placement. Several techniques exist for reflowing; for example, thermal conduction by heated belt. Dwell times vary between 50 and 300 seconds depending on heating method. Typical reflow temperatures range from 215 to 250 °C.

Preheating is necessary to dry the paste and evaporate the binding agent. Preheating duration: 45 minutes at 45 $^{\circ}$ C.

WAVE SOLDERING

Wave soldering techniques can be used for all SO packages if the following conditions are observed:

- A double-wave (a turbulent wave with high upward pressure followed by a smooth laminar wave) soldering technique should be used.
- The longitudinal axis of the package footprint must be parallel to the solder flow.
- The package footprint must incorporate solder thieves at the downstream end.

During placement and before soldering, the package must be fixed with a droplet of adhesive. The adhesive can be applied by screen printing, pin transfer or syringe dispensing. The package can be soldered after the adhesive is cured.

Maximum permissible solder temperature is 260 °C, and maximum duration of package immersion in solder is 10 seconds, if cooled to less than 150 °C within 6 seconds. Typical dwell time is 4 seconds at 250 °C.

A mildly-activated flux will eliminate the need for removal of corrosive residues in most applications.

REPAIRING SOLDERED JOINTS

Fix the component by first soldering two diagonallyopposite end leads. Use only a low voltage soldering iron (less than 24 V) applied to the flat part of the lead. Contact time must be limited to 10 seconds at up to 300 °C. When using a dedicated tool, all other leads can be soldered in one operation within 2 to 5 seconds between 270 and 320 °C.
