32-Bit to 32/16/8-Bit Dynamic READ/WRITE Bus Sizer

The MC68150 Dynamic Bus Sizer is designed to allow the 32-bit MC68/LC/EC040 bus, or other 16- to 32-bit processors, to communicate bi-directionally with 32-, 16-, or 8-bit peripherals and memories. It dynamically recognizes the size of the selected peripheral/memory and then writes or reads the appropriate data to or from that location. Systems designed using the bus sizing feature built into the 68030 can now be easily upgraded to the 68/EC040 by incorporating the MC68150. The 68150 comes in two speed grades: 25/33MHz and 40MHz. These frequencies correspond to their 68040 counterparts. The two grades should be ordered as the MC68150FN33 and MC68150FN40, respectively.

Typical operations which call for bus sizing are booting up instructions from 8-bit ROM (EPROM, EEPROM, etc.) and communicating with 8-bit SRAM's for scratch pad memory storage during interrupt operations. The dynamic property is necessary because the processor does not always know the size of the peripheral it is accessing, as in the case of communicating with a 16-bit VME bus. The MC68150 can also be used to separate a 32-bit "Fast Bus" and an 8-, 16-, or 32-bit "Slow Bus". (See Figure 3)

Features

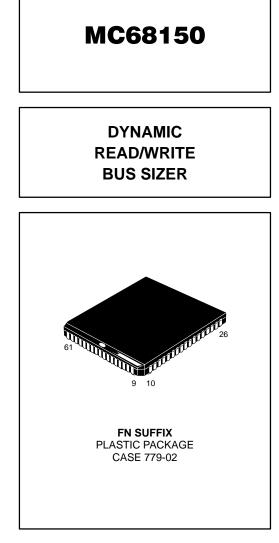

- Allows MC68/LC/EC040 or Other '040 Based Controllers or 68060 to Communicate With 8-Bit Memories and Any MC68XXX Peripheral
- Also Allows Other RISC Processors to Communicate With 8-Bit and 16-Bit Peripherals
- Recognizes the Port (Peripheral) Size Dynamically
- Generates Byte/Word Address to the Dynamic Port
- Generates Byte WRITE Enable Signals For 16- and 8-bit Ports
- Sends a Transfer Acknowledge Signal to the Processor When a Transfer Is Completed
- Synchronization of Data Transfer on Dynamic Port Allows Use of Any Speed Peripheral

1. Overview of Chip Operation

Each acc<u>ess</u> through the MC68150 is started with a chip select (CS) assertion to the MC68150 - which is generated when a PAL sees a TS signal from the '040 - and completed with a transfer acknowledge (TA) from the MC68150 to the MC68040. The MC68150 has two distinct buses, the MPU bus and the peripheral bus. The MPU bus connects to the process or and includes the transfer control signals (A1, A0, SIZ1, SIZ0, and R/W), the chip select (CS), the transf<u>er acknowledge (TA) and the data bus signals (D31-D0)</u>. The peripheral bus consists <u>of the peripheral transfer control signals (SWE, UWE, LWE, DS, PA1, PA0)</u>, and the peripheral transfer acknowledge signals (DSACK1, DSACK0) and the peripheral data bus (PD31-PD16).

If a 32-bit peripheral bus is used, then two additional transceivers (e.g. MC74F245) are required for the lower two bytes of the data. These transceivers would be connected to the PD15-PD<u>0</u> pins on the peripheral side and to the corresponding D15-D0 pins on the MPU bus. The transfer direction is controlled with the R/W signal of the processor. The transceivers are enabled only when making an access to a 32-bit port. The D15-D0 pins of the MPU bus on the MC68150 are always disabled until the port size is known, to avoid bus contention when the port is 32-bits.

An access refers to the complete transaction through the MC68150. On the peripheral bus, an access is split into one, two, or four separate transfers.

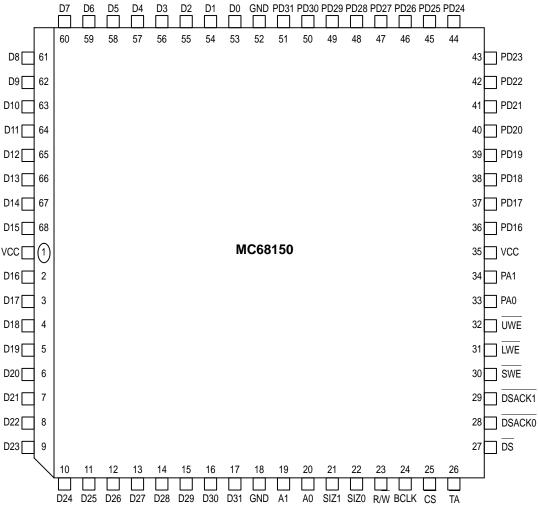

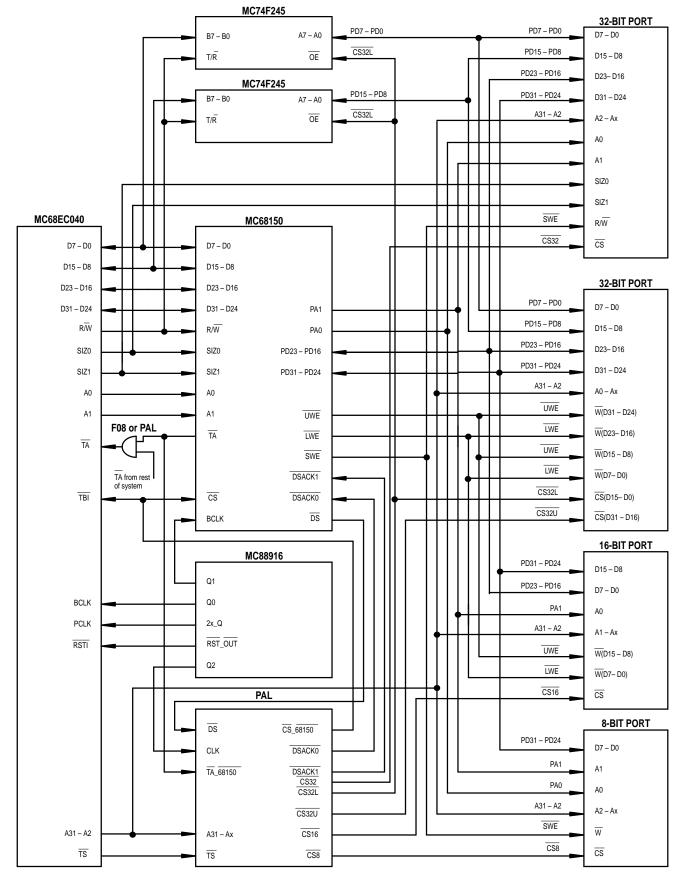

11/94

PIN DESCRIPTIONS

Pin	I/O	Description
BCLK	I	Bus clock — the main system clock (from MC88916)
D31–D0	I/O	Data bits on the 32-bit '040 bus
PD31–PD16	I/O	Peripheral data — data bits on the 8/16/32-bit peripheral side; PD15–PD0 do not exist for a 32-bit access, these require two F245 transceivers
PA1, PA0	0	Peripheral address — address bits indicating the byte being accessed on the peripheral side (00 = MSB, 11 = LSB)
UWE, LWE	0	Upper (PD31–PD24), lower (PD23–PD16) write enables on the peripheral side significant for 16-bit ports (WRITE)
SWE	0	Single write enable on the peripheral-bit side for 8-bit ports (WRITE)
DS	0	Data strobe indicates data can be put on the peripheral bus to be read by the '040 (READ) or is valid to be written on the peripheral bus (WRITE)
DSACK1, DSACK0	I	Data transfer acknowledge. HH inserts wait states in the current bus cycle. HL indicates the peripheral bus size is 8-bits. LH indicates peripheral bus size is 16-bits. LL indicates the peripheral bus is 32-bits. Recognition of these signals is what allows for "dynamic" bus sizing
SIZ1, SIZ0	I	Indicates the size of the MPU bus access. HH or LL = 32-bits (long word); HL = 16-bits (word); LH = 8-bits (byte)
A1, A0	I	'040 Address bits, Indicates the byte offset of the '040 access (which byte is accessed: HH = D7-D0; HL = D15-D8; LH = D23-D16; LL = D31-D24)
CS	I	Chip select, tells the 68150 that a transfer is starting or ending
ТА	0	Transfer acknowledge indicates the 68150 has completed the transfer
R/W	I	READ/WRITE, tells the 68150 if it is a read or write transfer

TYPICAL SYSTEM CONFIGURATION

A 68040 system using the MC68150 for dynamic bus sizing consists minimally of the MC68040 microprocessor, the MC68150, a PAL for timing control, and various size memory devices. When a 32-bit port is required, two F245's must be used to buffer the PD15–PD0 bits to the D15–D0 bits of the '040, since the MC68150 does not support these bits. The typical system configuration (Figure 2) illustrates communication between a 68040 and 8-, 16-, and 32-bit peripheral chips.

Design Guidelines

- · Peripheral data connections are the same as for a 68030
 - Connect PD31:24 for 8-bit port
 - Connect PD31:24 for upper byte 16-bit port
 - Connect PD23:16 for lower byte 16-bit port
 - Connect PD31:24 for upper-upper byte 32-bit port
 - Connect PD23:16 for upper-middle byte 32-bit port
 - Connect PD15:8 for lower-middle byte 32-bit port
 - Connect PD7:0 for lower-lower byte 32-bit port
- 32-bit ports require transceivers or latched transceivers for PD15:0

 The MC68150 only passes the upper 16 data bits on a 32-bit transfer
- 68150 does not support burst mode
 - One way to handle this is to connect \overline{TA} of the 68150 to \overline{TBI} of the 68040

2. MC68040 BUS OPERATION

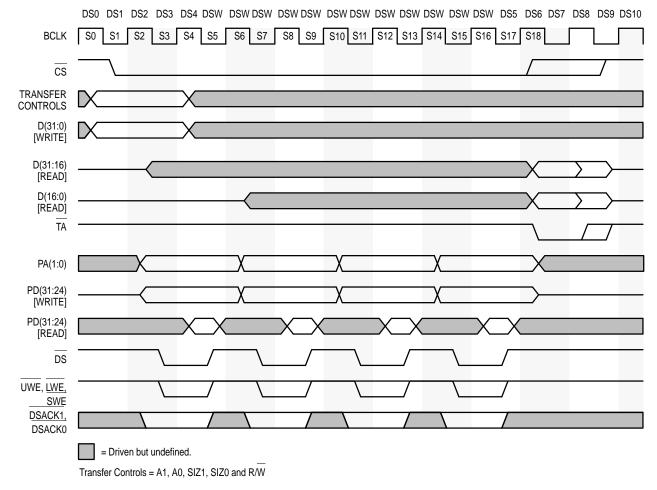

An access is divided into multiple states. Each state represents half a clock period. All even states are defined when BCLK is High, all odd states are defined when BCLK is low. A clock edge is referenced by the state that follows the clock edge. All rising edges are referenced by odd number states. DS0 is the first state of an access. DSW represents a wait state or a mid-access transfer state. A wait state indicates an access is occurring, but that the MC68150 is waiting on the peripheral to complete the transaction. Note that the peripheral and MPU states are distinct, though related, to each other. The peripheral states start with S0. Figure 4 is an example transfer with the states marked.

2.1 Access Start

The MC68040 begins an access by asserting the transfer control signals and transfer start (TS). The transfer control signals are held by the MC68040 throughout the access. The transfer start is asserted around only one rising edge of the clock (BCLK). The chip select (CS) for the MC68150 is asserted while the MC68040 transfer control signals are input to the MC68150.

_____ The transfer control signals (A1, A0, SIZ1, SIZ0, R/W) must all be valid a set-up time before the rising edge of BCLK on which CS recognized (DS2). If the transfer control signals change states during this set-up time, the MC68150 operation is unpredictable. The transfer control signals must be held valid until at least DS4. If the CS switches during the set-up time before the rising edge of DS2, then the access may not be recognized until the next clock edge. Once asserted, CS must be held asserted until the end of the access.

During a write access, the data signals (D(31:0)) must be valid a set-up time before the rising edge of DS2. The '040 data is latched into the 68150 off the DS2 rising clock edge (as long as CS is recognized as described above). This latched data is internally held by the 68150 until CS is negated at the end of a transfer.

2.2 Early Access Termination

An access through an MC<u>681</u>50 can be terminated before completion by negating CS early. The CS negation is recognized on a rising edge of BCLK. The CS **early negation** is used when the access should be ignored, such as when a bus error occurs. Any data transferred through the MC68150 is lost when an early <u>acc</u>ess negation occurs. If the access must be completed at a later time, the entire access must be repeated. To guarantee that TA is not asserted during early negation, CS must be negated before DS6.

For peripherals that can be read or written to twice, special care must be taken in aborting the 68150 access.

2.3 Early Release of the MPU Bus

Though early MPU bus release is not economical for most applications, it may allow an incremental improvement in performance at the expense of additional logic.

The transfer control signals (A1, A0, SIZ1, SIZ0, R/W) are held valid at least until DS4. During a write access, the data signals are held valid at least until DS4. After this hold time, the transfer control signals may change without affecting operation as long as CS remains asserted. This allows the MC68150 to release the MPU bus before the access is complete on the peripheral side of the MC68150. During a read access, early release is of limited use, because the MC68040 will not be able to use the bus until the peripheral data has been read. On a write, early MPU bus release does allow the MC68040 to continue with the next operation while the MC68150 completes the access.

When using this <u>ea</u>rly release feature, a bus error could be difficult to handle. If the peripheral asserts a bus error after the MC68040 receives a TA, meaning the transfer is complete, then a subsequent bus error assertion to the MC68040 will not match the offending address with the bus error address. This can be handled by software or hardware that reads a bit to see if the bus error is coming from the MC68150.

Another consideration in using early bus release is the handling of back to back transfers and transfer acknowledges. The chip select logic for the MC68150 must recognize when a second access occurs while completing an access on the peripheral side. The CS must be negated for one rising edge of BCLK between accesses. The transfer acknowledge from the MC68150 signals the end of the access. If early bus release is used, then the transfer acknowledge generated by the MC68150 should not be sent to the MC68040.

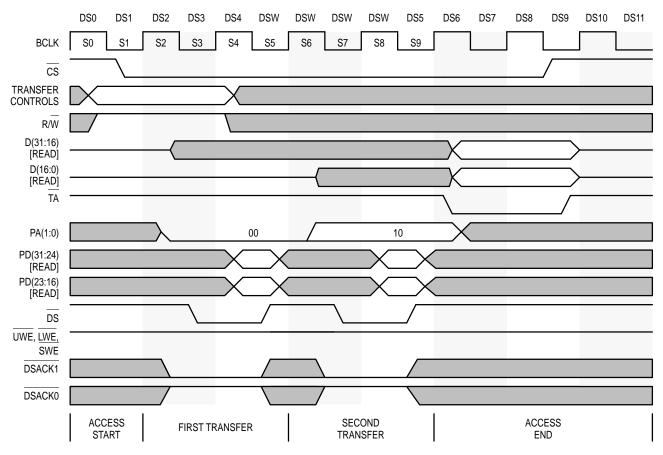

Figure 5. 32-Bit '040 READ from 16-Bit Peripheral With Asynchronous Termination

2.4 Access Termination

The final transfer on the peripheral side of the MC68150 occurs during DS5. The MC68150 access is normally terminated by the MC68150 asserting TA during DS6. Once the TA is asserted, TA is held asserted until at least DS8. The MC68150 negates TA **asynchronously** if CS is negated <u>after</u> DS7; an example of asynchronous termination is shown in Figure 5. An abnormal MC68150 termination occurs when the CS is negated before DS6. See early access termination for more details.

For a normal access, CS is held asserted until at least DS6. TA negation is synchronous to the rising edge of DS8 if CS meets a set-up to a DS8 rising BCLK edge. Asynchronous termination is defined as any CS negation beyond the DS8 rising BCLK edge. In this case the TA occurs a delay after the CS negation, because it is asynchronous termination.

____ During a read access, the data being presented to the MC68040 is held for at least one rising edge of BCLK (DS8). When <u>CS</u> is negated, the MPU data bus goes to high impedance. If the data must be held longer than a single period, then asynchronous TA negation is necessary.

2.5 MPU Bus Idle State

CS must remain high for <u>one</u> rising edge of BCLK between each access. This is guaranteed by the MC68040 if CS is asserted on the clock edge following TS assertion (or later) <u>on</u> all accesses through the MC68150. When the MPU bus is idle (between accesses), the D(31:0) are in high impedance and TA is negated.

3. PERIPHERAL BUS OPERATION

The peripheral access is divided into one or more transfers. The transfers are divided into multiple states. Each state represents half a clock period. All even states are the BCLK HIGH half of the clock period. All odd states are the BCLK LOW half of the clock period. A clock edge is referenced by the state that follows the clock edge. All rising edges are referenced by even number states. All falling edges are referenced by odd number states. S0 is the first state of a peripheral access. Note that the peripheral and MPU states are distinct, though related to each other.

3.1 Initial Transfer Start

A transfer starts off the rising edge of BCLK following the CS assertion (S2). The starting address of the transfer (PA1, PA0) is asserted during S2. The MC68040 A(31:2) are routed past the MC68150, directly to the peripheral bus. Buffers can be used to minimize loading on the MC68040 address bus. If the access is a write, the peripheral data bus (PD(31:16)) is driven during S2.

The starting data strobe (DS) is asserted during S3. If the access is a write, the starting write enables (SWE, UWE, and LWE) are also asserted during S3. SWE is the write enable for 8-bit peripherals. The SWE is asserted for every transfer of a write access. It indicates the data on PD(31:24) is valid and ready to be written to the 8-bit peripheral. UWE and LWE are the write enables for 16-bit peripherals. UWE indicates the data on PD(31:24) is valid and ready to be written to the 16-bit peripheral. LWE indicates the data on PD(31:24) is valid and ready to be written to the 16-bit peripheral. LWE indicates the data on PD(31:24) is valid and ready to be written to the 16-bit peripheral.

A 32-bit port <u>can generate</u> write enables from the MC68040 normally (A1, A0, <u>SIZ1</u>, SIZ<u>0 and</u> R/W). These write enables can be qualified with SWE or DS for the 32-bit peripheral. An alternativ<u>e is to</u> use the UWE and LWE in <u>conjunction</u> with the PA1 and PA0. If it is a 32-bit access (SIZ1 and SIZ0 = HH or LL), th<u>en apply</u> UWE to PD(31:24), PD(15:8) and LWE to PD(23:16), PD(7:0). If it is a 16-bit access (SIZ1 and SIZ0 = HL), then apply UWE to PD(31:24) and LWE to PD(23:16).

3.2 Initial Transfer Termination

Starting with S2, the MC68150 monitors the data strobe acknowledge signals (DSACK1, DSACK0) for the access termination. Wait states are inserted into the access by maintaining DSACK1 and DSACK0 HIGH. The DSACK1 and DSACK0 are sampled on the falling edge of BCLK. DSACK1 and DSACK0 must remain valid for two successive falling edges of BCLK to be recognized. If the access is a read, the PD(31:16) must be valid a set-up before the falling edge between S4 and S5. The PD(31:16) must be held valid a hold time into S5. The DSACK1 and DSACK0 are first sampled during S2. The DSACK1 and DSACK0 are then continuously sampled each falling edge of BCLK until the entire access is completed. This means the fastest initial transfer is two clocks (starting S2 and ending S4).

The size of the peripheral port is indicated by the DSACK1 and DSACK0. The port size must be indicated on the first transfer and is the port size for the remainder of the access. Once the peripheral port size is indicated on the first transfer, all subsequent transfers should be terminated with the same port size indication. If another port size is indicated on subsequent transfers of the same access, the MC68150 operation is not guaranteed nor predictable. Depending upon the conditions, the MC68150 may either

ignore the port size change on subsequent transfers or accept the subsequent transfers as a transfer of the original port size. If the MC68150 ignored the improper transfer, the DS is not negated. If the MC68150 accepted the improper transfer as an original port size transfer, DS negates normally. If a different port size is indicated on subsequent transfers, the changing of DSACK1 and DSACK0 states on subsequent transfers may or may not insert wait states into the access.

When a valid DSACK1 and DSACK0 state has been held for two consecutive <u>falling edges</u> of <u>BCLK</u>, the initial transfer is ended (falling edges of S3 and S5). DS is negated during S5. If the access is a write, SWE, UWE and LWE are all negated during S5. PA1 and PA0 are held valid until S6. If the access is a write, PD(31:16) are held valid until S6.

CS	DSACK1	DSACK0	
н	Х	Х	No Access
L	L	L	Complete 32-Bit Access
L	L	н	Complete 16-Bit Access
L	н	L	Complete 8-Bit Access
L	Н	Н	Insert Wait States

Table 3. DSACK1 AND DSACK0 DECODE LOGIC

3.3 Subsequent Access Termination

If additional transfers are required to complete an access (e.g. a long word access to a byte port requires <u>four transfers to</u> com<u>plete</u>), then PA1 and PA0 are changed during S6. If the access is a write, PD(31:16) is changed during S6. DS, SWE, UWE and LWE are asserted during S7. The DSACK1 and DSACK0 are sampled again for the subsequent transfer during S6.

If the access is a read, the PD(31:16) must be valid a set-up before the falling edge between S8 and S9. The PD(31:16) must be held valid a hold time into S9. DS, SWE, UWE and LWE are negated during S9.

Subsequent transfers continue in the same manner with S10 and S14 replacing S6 above, S11 and S15 replacing S7 above, S13 and S17 replacing S9 above, and S14 and S18 replacing S10. Figures 13 and 14 are examples of 32-bit '040 access from/to an 8-bit port, read and write respectively. Both require four sequential data transfers to complete the access.

On a write, the PD(31:16) bus goes into high impedance when <u>TA asserts (DS6). To hold the data valid on the PD(31:16)</u> bus beyond th<u>e normal access end</u>, wait states must be inserted using DSACK1, DSACK0 = HH on the last transfer. The wait states will delay TA assertion.

3.4 Peripheral Bus Idle State

The MC68150 enters an idle state on the peripheral bus on the rising edge of BCLK after the last transfer is terminated. When the peripheral bus is idle, DS, UWE, LWE and SWE are all negated. PA1 and PA0 are driven, but undefined. PD(31:16) are in high impedance. DSACK1 and DSACK0 are ignored.

3.5 Peripheral Bus Asynchronous Operation (Only for operation independant of BCLK non–680X0 processors. See AC Specifications 22–34 in lieu of specs 1–21)

The MC68150 peripheral bus has both asynchronous and sychronous operations. The asynchronous operation allows the user to operate the peripheral bus independently of the BCLK. The synchronous operation requires close attention to the BCLK set-up and hold times.

An as<u>vnch</u>ronous transfer on the MC68150 begins with the assertion of DS by the MC68150. If the access is a write, SWE, UWE and LWE are asserted at the same time as DS. PA1 and PA0 are valid before the DS assertion. PD(31:16) are driven and valid before DS assertion. To avoid bus contention on the peripheral bus, the R/W from the MPU can be used.

The DSACK1 and DSACK0 assertions must be within the asynchronous skew specification. If one of the DSACK signals is asserted on one falling edge, the asynchronous skew specification ensures that the other DSACK signal is valid before the next falling edge. Because the DSACK signals can be changing on a falling BCLK edge, an additional wait state may be incurred. DSACK1 and DSACK0 can be negated when DS is negated.

_____If the access is a write, the UWE, LWE and SWE negate at the same time as DS. PD(31:16) change state after the DS, UWE, LWE and SWE are negated.

If the access is a read, PD(31:0) is valid after DSACK1 and DSACK0 are asserted and held until DS is negated.

MAXIMUM RATINGS*

Symbol	Parameter	Value	Unit
V _{CC}	DC Supply Voltage (Referenced to GND)	-0.3 to +7.0	V
VIN	DC Input Voltage (Referenced to GND)	-0.5 to +7.0	V
Vout	DC Output Voltage (Referenced to GND)	–0.5 to V _{CC} + 0.5	V
I _{IN}	DC Input Current, Per Pin	±20	mA
IOUT	DC Output Sink/Source Current, Per Pin	±35	mA

T _A	Operating Ambient Temperature Range	-40 to +85	°C

* Maximum Ratings are those values beyond which damage to the device may occur. Functional operation should be restricted to the Recommended Operating Conditions.

RECOMMENDED OPERATING CONDITIONS

Symbol	Parameter	Min	Max	Unit
V _{CC}	DC Supply Voltage (Referenced to GND)	4.5	5.5	V
V _{IN} , V _{OUT}	DC Input Voltage, Output Voltage (Referenced to GND)	0	V _{CC}	V
T _A	Operating Ambient Temperature Range	-40	85	°C
IOL/IOH	Output Current, LOW/HIGH (Control Pins) (Data Pins)		±16 ±5	mA

OTHER CHARACTERISTICS

Symbol	Parameter	Conditions	Ratings	Unit
C _{IN}	Input Capacitance	VI = 0V or VCC	8.5	pF
COUT	Output Capacitnace	VI = 0V or VCC		pF
C _{I/O}	Input/Output Capacitance	$V_I = 0V \text{ or } V_{CC}$		pF
ILATCHUP	Latchup Current		>500	mA
VESD	Electrostatic Discharge Voltage		8,000	V
PD	Power Dissipation in Still Air (Calculated at Worst Case)		530	mW

NOTE: Rating values are design targets. Actual performance will be noted upon completion of characterization.

ICC versus FREQUENCY

	N	o Load (50pF On 25°C I _{CC} (mA)	ly)	Loaded (50pF/500Ω) 25°C I _{CC} (mA)			
Frequency (MHz)	4.5	5.0	5.5	4.5	5.0	5.5	
1	2	4	6	65	73	82	
10	13	16	20	75	83	93	
20	25	29	35	85	95	106	
30	38	43	50	95	106	120	
40	51	59	67	105	120	135	

DC SPECIFICATIONS

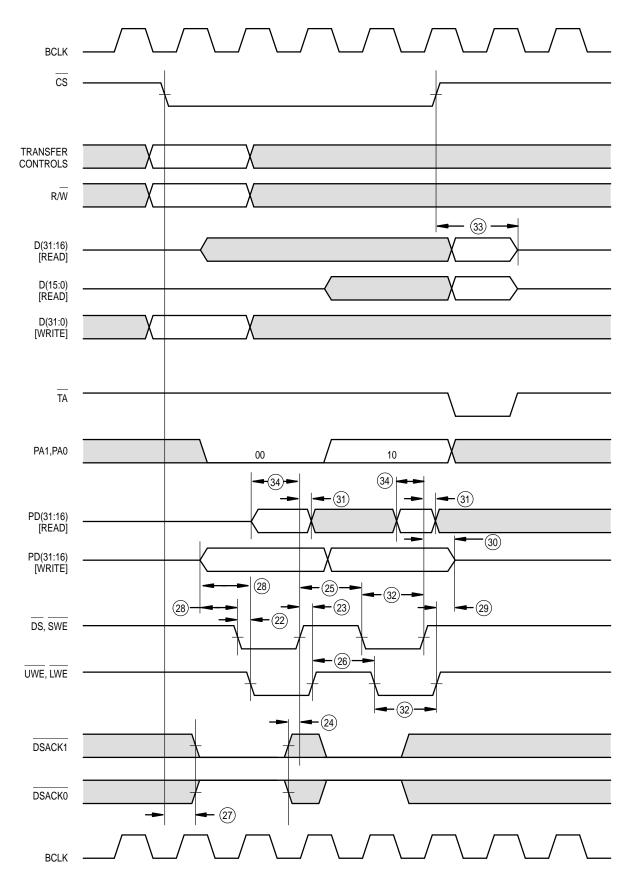

Symbol	Characteristic	Min	Мах	Unit	Condition
VIH	Input HIGH Voltage	2.0	VCC	V	$V_{CC} = 5V$
VIL	Input LOW Voltage	GND	0.8	V	$V_{CC} = 5V$
I _{IN}	Input Leakage Current SIZ1, SIZ0, A1, A0, CS, DSACK1, DSACK0, R/W, BCLK		±20	μA	$V_{IN} = 0.5V/2.4V,$ $V_{CC} = 5.25V$
I _{OZ}	Hi-Impedance (Off-State) Leakage Current D(31:0), PD(31:16)		±20	μA	$V_{IN} = V_{IH}/V_{IL}$ $V_O = GND/V_{CC}$
∆ICCT (BCLK)	Additional Maximum ICC/Input BCLK Only		7.5	mA	V _{IH} = V _{CC} –2.1V, V _{CC} = 5.25V
∆ICCT	Additional Maximum ICC/Input SIZ1, SIZ0, A1, A0, CS, DSACK1, DSACK0, R/W		1.5	mA	V _{IH} = V _{CC} –2.1V, V _{CC} = 5.25V
Vou	Output High Voltage: For D(31:0), PD(31:16)	2.4		V	I _{OH} = -5.0mA, V _{CC} = 4.75V
^V OH	Output High Voltage: For DS, SWE, UWE, LWE, PA1, PA0, TA	2.4		V	I _{OH} = -16mA, V _{CC} = 4.75V
Ve	Output Low Voltage: For D(31:0), PD(31:16)		0.5	V	I _{OL} = +5.0mA, V _{CC} = 4.75V
VOL	Output Low Voltage: For DS, SWE, UWE, LWE, PA1, PA0, TA		0.5	V	I _{OL} = +16mA, V _{CC} = 4.75V
ICC	Maximum Quiescent Supply Current		100	μA	V _{CC} = 5.25V

TIMING DIAGRAM EXAMPLES FOR ALL POSSIBLE TRANSFERS

Figures 13 through 56 depict timing waveforms of all possible transfers, including all address combinations. Each pair of figures includes a read transfer and its corresponding write transfer. Figures 13–20 cover all 32-bit '040 bus transfers (to each port size), Figures 21–32 cover all 16-bit '040 bus transfers, and Figures 33–56 cover all 8-bit '040 bus transfers. Specific timing values have been left off these figures; refer to Figures 6–8 and the AC Specifications for this information.
