

CYPRESS

CY26501/CY26502

533-MHz Direct Rambus™ Clock Generator

Features

- Differential clock source for Direct Rambus™ memory subsystem for up to 1066-MHz data transfer rate
- Provide synchronization flexibility: the Rambus® Channel can optionally be synchronous to an external system or processor clock
- Power managed output allows Rambus Channel clock to be turned off to minimize power consumption for mobile applications
- Cycle to Cycle Jitter below 50 ps
- Low-power CMOS design packaged in a 24-pin, 150-mil SSOP package
- Support up to 533MHz for Commercial temperature and 400 MHz for Industrial temperature.

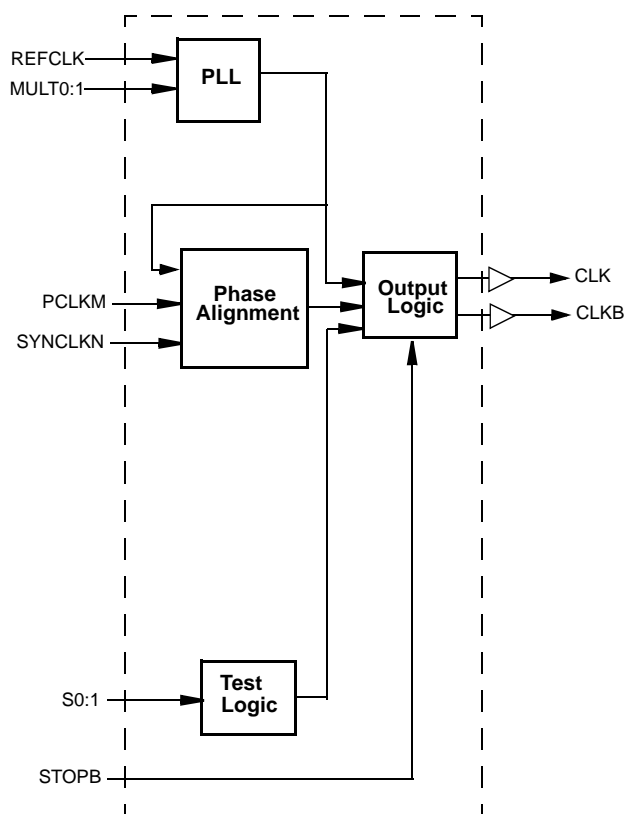

Overview

The Cypress CY26501 and CY26502 provide the differential clock signals for a Direct Rambus memory subsystem. It includes signals to synchronize the Direct Rambus Channel clock to an external system clock but can also be used in systems that do not require synchronization of the Rambus clock.

Key Specifications

Supply Voltage: $V_{DD} = 3.3V \pm 0.165V$
 Operating Temperature(Commercial): $0^{\circ}C$ to $+70^{\circ}C$
 Operating Temperature(Industrial): $-40^{\circ}C$ to $+85^{\circ}C$
 Input Threshold: 1.5V typical
 Maximum Input Voltage: $V_{DD} + 0.5V$
 Maximum Input Frequency: 100 MHz
 Output Duty Cycle: 40/60% worst case
 Output Type: Rambus signaling level (RSL)

Pin Definitions

Pin Name	Pin No.	Pin Type	Pin Description																				
REFCLK	2	I	Reference Clock Input: Reference clock input, normally supplied by a system frequency synthesizer (Cypress W133).																				
PCLKM	6	I	Phase Detector Input: The phase difference between this signal and SYNCLKN is used to synchronize the Rambus Channel Clock with the system clock. Both PCLKM and SYNCLKN are provided by the Gear Ratio Logic in the memory controller. If Gear Ratio Logic is not used, this pin would be connected to Ground.																				
SYNCLKN	7	I	Phase Detector Input: The phase difference between this signal and PCLKM is used to synchronize the Rambus Channel Clock with the system clock. Both PCLKM and SYNCLKN are provided by the Gear Ratio Logic in the memory controller. If Gear Ratio Logic is not used, this pin would be connected to Ground.																				
STOPB	11	I	Clock Output Enable: When this input is driven to active LOW, it disables the differential Rambus Channel clocks.																				
PWRDNB	12	I	Active LOW Power-Down: When this input is driven to active LOW, it disables the differential Rambus Channel clocks and places the CY26501/CY26502 in power-down mode.																				
MULT 0:1	15, 14	I	PLL Multiplier Select: These inputs select the PLL prescaler and feedback dividers to determine the multiply ratio for the PLL for the input REFCLK: <table><thead><tr><th>MULT0</th><th>MULT1</th><th>CY26501 PLL/REFCLK</th><th>CY26502 PLL/REFCLK</th></tr></thead><tbody><tr><td>0</td><td>0</td><td>4.5</td><td>4</td></tr><tr><td>0</td><td>1</td><td>6</td><td>6</td></tr><tr><td>1</td><td>1</td><td>8</td><td>8</td></tr><tr><td>1</td><td>0</td><td>5.333</td><td>5.333</td></tr></tbody></table>	MULT0	MULT1	CY26501 PLL/REFCLK	CY26502 PLL/REFCLK	0	0	4.5	4	0	1	6	6	1	1	8	8	1	0	5.333	5.333

NC	19	-	No Connect																				
VDDIR	1	RefV	Reference for REFCLK: Voltage reference for input reference clock.																				
VDDIPD	10	RefV	Reference for Phase Detector: Voltage reference for phase detector inputs and STOPB.																				
VDD	3, 9, 16, 22	P	Power Connection: Power supply for core logic and output buffers. Connected to 3.3V supply.																				
GND	4, 5, 8, 13, 17, 21	G	Ground Connection: Connect all ground pins to the common system ground plane.																				

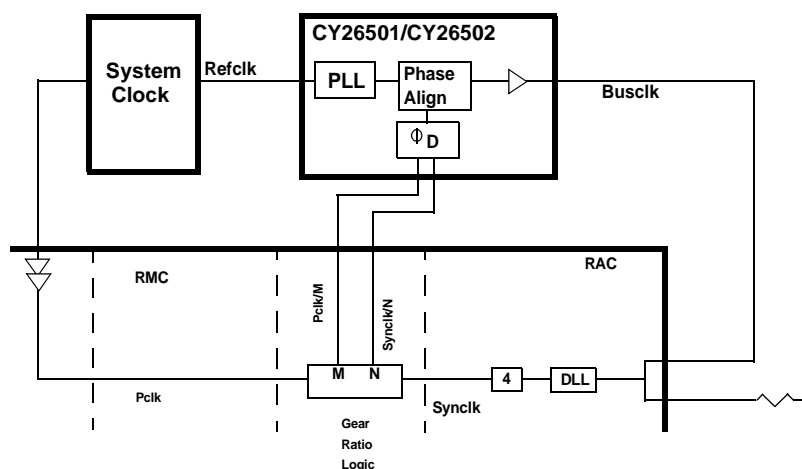

Figure 1. DDLL System Architecture

DDLL System Architecture and Gear Ratio Logic

Figure 1 shows the Distributed Delay Lock Loop (DDLL) system architecture, including the main system clock source, the Direct Rambus Clock Generator (DRCG), the core logic that contains the Rambus Access Cell (RAC), the Rambus Memory Controller (RMC), and the Gear Ratio Logic. (This diagram abstractly represents the differential clocks as a single Busclk wire.)

The purpose of the DDLL is to frequency-lock and phase-align the core logic and Rambus clocks (Pclk and Synclk) at the RMC/RAC boundary in order to allow data transfers without incurring additional latency. In the DDLL architecture, a PLL is used to generate the desired Busclk frequency, while a distributed loop forms a DLL to align the phase of Pclk and Synclk at the RMC/RAC boundary.

The main clock source drives the System Clock (Pclk) to the core logic, and also drives the Reference Clock (Refclk) to the DRCG. For typical Intel® architecture platforms, Refclk will be half the CPU front side bus frequency. A PLL inside the DRCG multiplies Refclk to generate the desired frequency for Busclk, and Busclk is driven through a terminated transmission line (Rambus Channel). At the mid-point of the channel, the RAC senses Busclk using its own DLL for clock alignment, followed by a fixed divide-by-4 that generates Synclk.

Pclk is the clock used in the Memory Controller (RMC) in the core logic, and Synclk is the clock used at the core logic inter-

face of the RAC. The DDLL, together with the Gear Ratio Logic, enables users to exchange data directly from the Pclk domain to the Synclk domain without incurring additional latency for synchronization. In general, Pclk and Synclk can be of different frequencies, so the Gear Ratio Logic must select the appropriate M and N dividers such that the frequencies of Pclk/M and Synclk/N are equal. In one interesting example, Pclk = 133 MHz, Synclk = 100 MHz, and M = 4 while N = 3; giving Pclk/M = Synclk/N = 33 MHz. This example of the clock waveforms with the Gear Ratio Logic is shown in Figure 2.

The output clocks from the Gear Ratio Logic, Pclk/M, and Synclk/N are output from the core logic and routed to the DRCG Phase Detector inputs. The routing of Pclk/M and Synclk/N must be matched in the core logic as well as on the board.

After comparing the phase of Pclk/M vs. Synclk/N, the DRCG Phase Detector drives a phase aligner that adjusts the phase of the DRCG output clock, Busclk. Since everything else in the distributed loop is fixed delay, adjusting Busclk adjusts the phase of Synclk and thus the phase of Synclk/N. In this manner the distributed loop adjusts the phase of Synclk/N to match that of Pclk/M, nulling the phase error at the input of the DRCG Phase Detector. When the clocks are aligned, data can be exchanged directly from the Pclk domain to the Synclk domain.

Table 1 shows the combinations of Pclk and Busclk frequencies of greatest interest, organized by Gear Ratio.

Figure 2. Gear Ratio Timing Diagram

Table 1. Supported Pclk and Busclk Frequencies, by Gear Ratio

Pclk	Gear Ratio and Busclk				
	2.0	1.5	1.33	1.0	0.66
67 MHz				267 MHz	400 MHz
100 MHz			300 MHz	400 MHz	
133 MHz	267 MHz	356 MHz	400 MHz	533 MHz	
150 MHz		400 MHz			
200 MHz	400 MHz	533 MHz			

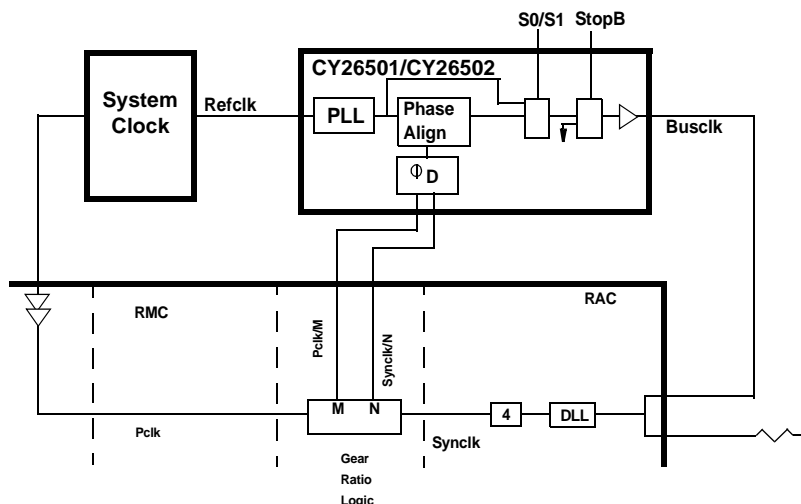

Figure 3. DDLL Including Details of DRCG

Figure 3 shows more details of the DDLL system architecture, including the DRCG output enable and bypass modes.

Phase Detector Signals

The DRCG Phase Detector receives two inputs from the core logic, PclkM (Pclk/M) and SyncN (SyncN/N). The M and N dividers in the core logic are chosen so that the frequencies of PclkM and SyncN are identical. The Phase Detector detects the phase difference between the two input clocks, and drives the DRCG Phase Aligner to null the input phase error through the distributed loop. When the loop is locked, the input phase error between PclkM and SyncN is within the specification $t_{ERR,PD}$ given in Table 14 after the lock time given in the State Transition Section.

The Phase Detector aligns the rising edge of PclkM to the rising edge of SyncN. The duty cycle of the phase detector input clocks will be within the specification $DC_{IN,PD}$ given in Table 13. Because the duty cycles of the two phase detector input clocks will not necessarily be identical, the falling edges of PclkM and SyncN may not be aligned when the rising edges are aligned.

The voltage levels of the PclkM and SyncN signals are determined by the controller. The pin VDDIPD is used as the voltage reference for the phase detector inputs and should be connected to the output voltage supply of the controller. In some applications, the DRCG PLL output clock will be used

directly by bypassing the Phase Aligner. If PclkM and SyncN are not used, those inputs must be grounded.

Selection Logic

Table 2 shows the logic for selecting the PLL prescaler and feedback dividers to determine the multiply ratio for the PLL from the input Refclk. Divider A sets the feedback and divider B sets the prescaler, so the PLL output clock frequency is set by: $PLLclk = Refclk * A/B$.

Table 2. PLL Divider Selection

Mult0	Mult1	CY26501		CY26502	
		A	B	A	B
0	0	9	2	4	1
0	1	6	1	6	1
1	1	8	1	8	1
1	0	16	3	16	3

Table 3 shows the logic for enabling the clock outputs, using the StopB input signal. When StopB is HIGH, the DRCG is in its normal mode, and Clk and ClkB are complementary outputs following the Phase Aligner output (PAClk). When StopB is LOW, the DRCG is in the Clk Stop mode, the output clock drivers are disabled (set to Hi-Z), and the Clk and ClkB settle to the DC voltage $V_{X,STOP}$ as given in Table 14. The level of $V_{X,STOP}$ is set by an external resistor network.

Table 3. Clock Stop Mode Selection

Mode	StopB	Clk	ClkB
Normal	1	PAclk	PAclkB
Clk Stop	0	$V_{X,STOP}$	$V_{X,STOP}$

Table 4 shows the logic for selecting the Bypass and Test modes. The select bits, S0 and S1, control the selection of these modes. The Bypass mode brings out the full-speed PLL output clock, bypassing the Phase Aligner. The Test mode brings the Refclk input all the way to the output, bypassing both the PLL and the Phase Aligner. In the Output Test mode (OE), both the Clk and ClkB outputs are put into a high-impedance state (Hi-Z). This can be used for component testing and for board-level testing.

Table 4. Bypass and Test Mode Selection

Mode	S0	S1	Bypclk (int.)	Clk	ClkB
Normal	0	0	Gnd	PAclk	PAclkB
Output Test (OE)	0	1	-	Hi-Z	Hi-Z
Bypass	1	0	PLLclk	PLLclk	PLLclkB
Test	1	1	Refclk	Refclk	RefclkB

Table 5 shows the logic for selecting the Power-down mode, using the PwrDnB input signal. PwrDnB is active LOW (enabled when 0). When PwrDnB is disabled, the DRCG is in its normal mode. When PwrDnB is enabled, the DRCG is put into a powered-off state, and the Clk and ClkB outputs are three-stated.

Table 5. Power-down Mode Selection

Mode	PwrDnB	Clk	ClkB
Normal	1	PAclk	PAclkB
Power-down	0	GND	GND

Table of Frequencies and Gear Ratios

Table 6 shows several supported Pclk and Busclk frequencies, the corresponding A and B dividers required in the DRCG PLL, and the corresponding M and N dividers in the gear ratio logic. The column Ratio gives the Gear Ratio as defined Pclk/Synclk (same as M and N). The column F@PD gives the divided down frequency (in MHz) at the Phase Detector, where $F@PD = Pclk/M = Synclk/N$.

State Transitions

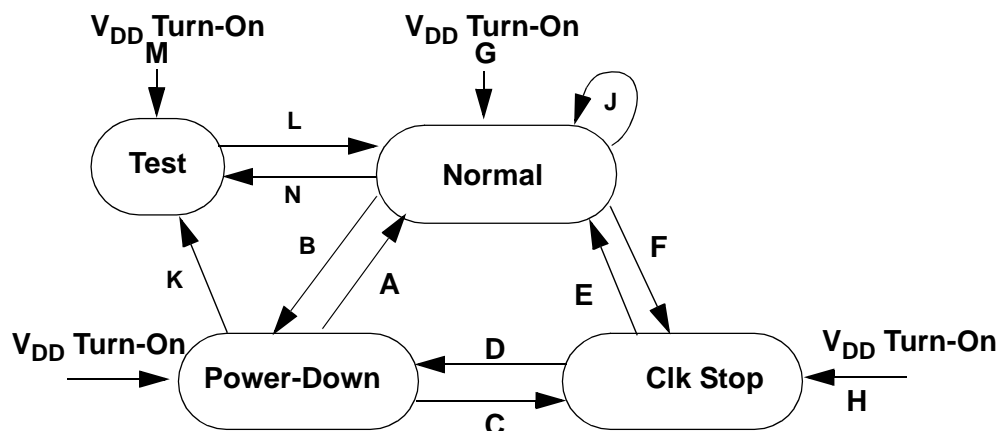

The clock source has three fundamental operating states. Figure 4 shows the state diagram with each transition labelled A through H. Note that the clock source output may NOT be glitch-free during state transitions.

Upon powering up the device, the device can enter any state, depending on the settings of the control signals, PwrDnB and StopB.

In Power-down mode, the clock source is powered down with the control signal, PwrDnB, equal to 0. The control signals S0 and S1 must be stable before power is applied to the device, and can only be changed in Power-down mode (PwrDnB=0). The reference inputs, V_{DDR} and V_{DDPD} , may remain on or may be grounded during the Power-down mode.

Table 6. Examples of Frequencies, Dividers, and Gear Ratios

Pclk	Refclk	Busclk	Synclk	A	B	M	N	Ratio	F@PD
67	33	267	67	8	1	2	2	1.0	33
100	50	300	75	6	1	8	6	1.33	12.5
100	50	400	100	8	1	4	4	1.0	25
133	67	267	67	4	1	4	2	2.0	33
133	67	400	100	6	1	8	6	1.33	16.7

Figure 4. Clock Source State Diagram

The control signals Mult0 and Mult1 can be used in two ways. If they are changed during Power-down mode, then the Power-down transition timings determine the settling time of the DRCG. However, the Mult0 and Mult1 control signals can also be changed during Normal mode. When the Mult control signals are “hot swapped” in this manner, the Mult transition timings determine the settling time of the DRCG.

In Clock Stop mode, the clock source is on, but the output is disabled (StopB asserted). The V_{DDP} reference input may remain on or may be grounded during the Clk Stop mode. The V_{DDR} reference input must remain on during the Clock Stop mode.

In Normal mode, the clock source is on, and the output is enabled.

Table 7 lists the control signals for each state.

Table 7. Control Signals for Clock Source States

State	PwrDnB	StopB	Clock Source	Output Buffer
Power-down	0	X	OFF	Ground
Clock Stop	1	0	ON	Disabled
Normal	1	1	ON	Enabled

Figure 5 shows the timing diagrams for the various transitions between states, and Table 8 specifies the latencies of each state transition. Note that these transition latencies assume the following:

- Refclk input has settled and meets specification shown in Table 13.
- Mult0, Mult1, S0 and S1 control signals are stable.

Figure 6. Multiply Transition Timing

Table 8. State Transition Latency Specifications

Transition	From	To	Transition Latency		Description
			Symbol	Max.	
A	Power-down	Normal	t_{POWERUP}	3 ms	Time from PwrDnB to Clk/ClkB output settled (excluding t_{DISTLOCK}).
C	Power-down	Clk Stop	t_{POWERUP}	3 ms	Time from PwrDnB until the internal PLL and clock has turned ON and settled.
K	Power-down	Test	t_{POWERUP}	3 ms	Time from PwrDnB to Clk/ClkB output settled (excluding t_{DISTLOCK}).
G	V_{DD} ON	Normal	t_{POWERUP}	3 ms	Time from V_{DD} is applied and settled until Clk/ClkB output settled (excluding t_{DISTLOCK}).
H	V_{DD} ON	Clk Stop	t_{POWERUP}	3 ms	Time from V_{DD} is applied and settled until internal PLL and clock has turned ON and settled.
M	V_{DD} ON	Test	t_{POWERUP}	3 ms	Time from V_{DD} is applied and settled until internal PLL and clock has turned ON and settled.
J	Normal	Normal	t_{MULT}	1 ms	Time from when Mult0 or Mult1 changed until Clk/ClkB output resettled (excluding t_{DISTLOCK}).
E	Clk Stop	Normal	t_{CLKON}	10 ns	Time from StopB until Clk/ClkB provides glitch-free clock edges.
E	Clk Stop	Normal	t_{CLKSETL}	20 cycles	Time from StopB to Clk/ClkB output settled to within 50 ps of the phase before CLK/CLKB was disabled.
F	Normal	Clk Stop	t_{CLKOFF}	5 ns	Time from StopB Φ to Clk/ClkB output disabled.
L	Test	Normal	t_{CTL}	3 ms	Time from when S0 or S1 is changed until CLK/CLKB output has resettled (excluding t_{DISTLOCK}).
N	Normal	Test	t_{CTL}	3 ms	Time from when S0 or S1 is changed until CLK/CLKB output has resettled (excluding t_{DISTLOCK}).
B,D	Normal or Clk Stop	Power-down	t_{POWERDN}	1 ms	Time from PwrDnB Φ to the device in Power-down.

Figure 5 shows that the Clk Stop to Normal transition goes through three phases. During t_{CLKON} , the clock output is not specified and can have glitches. For $t_{\text{CLKON}} < t < t_{\text{CLKSETL}}$, the clock output is enabled and must be glitch-free. For $t > t_{\text{CLKSETL}}$, the clock output phase must be settled to within

50 ps of the phase before the clock output was disabled. At this time, the clock output must also meet the voltage and timing specifications of Table 14. The outputs are in a high-impedance state during the Clk Stop mode.

Table 9. Distributed Loop Lock Time Specification

Parameter	Min.	Max.	Unit	Description
$t_{DISTLOCK}$		5	ms	Time from when Clk/ClkB output is settled to when the phase error between SyncN and PclkM falls within the $t_{ERR,PD}$ spec in Table 14.

Table 10. Supply and Reference Current Specification

Parameter	Description	Min.	Max.	Unit
$I_{POWERDOWN}$	"Supply" current in Power-down state ($PwrDnB = 0$)	--	800	μA
$I_{CLKSTOP}$	"Supply" current in Clk Stop state ($StopB = 0$)	--	100	mA
I_{NORMAL}	"Supply" current in Normal state ($StopB = 1, PwrDnB = 1$)	--	150	mA
$I_{REF,PWDN}$	Current at V_{DDIR} or V_{DDIPD} reference pin in Power-down state ($PwrDnB = 0$)	--	1	μA
$I_{REF,NORM}$	Current at V_{DDIR} or V_{DDIPD} reference pin in Normal or Clk Stop state ($PwrDnB = 1$)	--	1.5	mA

Table 11 represents stress ratings only, and functional operation at the maximums is not guaranteed.

Table 11. Absolute Maximum Ratings

Parameter	Description	Min.	Max.	Unit
$V_{DD, ABS}$	Max. voltage on V_{DD} with respect to ground	-0.5	4.0	V
$V_{I, ABS}$	Max. voltage on any pin with respect ground	-0.5	$V_{DD}+0.5$	V

Table 12 gives the nominal values of the external components and their maximum acceptable tolerance, assuming $Z_{CH} = 28\Omega$.

Table 12. External Component Values

Parameter	Description	Test Load	Recommended Value	Tolerance	Unit	Parameter

Table 13. Operating Conditions

Parameter	Description	Min.	Max.	Unit
V_{DD}	Supply Voltage	3.135	3.465	V
T_A	Ambient Operating Temperature	0	70	°C
$t_{CYCLE,IN}$	Refclk Input Cycle Time	10	40	ns
$t_{J,IN}$	Input Cycle-to-Cycle Jitter ^[2]	-	250	ps
DC_{IN}	Input Duty Cycle over 10,000 Cycles	40	60	% t_{CYCLE}
FM_{IN}	Input Frequency of Modulation	30	33	kHz
PM_{IN} ^[3]	Modulation Index for Triangular Modulation		0.6	%
	Modulation Index for Non-Triangular Modulation		0.5 ^[5]	%
$t_{CYCLE,PD}$	Phase Detector Input Cycle Time at PclkM & SyncN	30	100	ns
$t_{ERR,INIT}$	Initial Phase error at Phase Detector Inputs	-0.5	0.5	$t_{CYCLE,PD}$
$DC_{IN,PD}$	Phase Detector Input Duty Cycle over 10,000 Cycles	25	75	$t_{CYCLE,PD}$
$t_{I,SR}$	Input Slew Rate (measured at 20%-80% of input voltage) for PclkM, SyncN, and Refclk	1	4	V/ns
$C_{IN,PD}$	Input Capacitance at PclkM, SyncN, and Refclk ^[4]		7	pF
$\Delta C_{IN,PD}$	Input Capacitance matching at PclkM and SyncN ^[4]		0.5	pF
$C_{IN,CMOS}$	Input Capacitance at CMOS pins (excluding PclkM, SyncN, and Refclk) ^[4]		10	pF
V_{IL}	Input (CMOS) Signal Low Voltage		0.3	V_{DD}
V_{IH}	Input (CMOS) Signal High Voltage	0.7		V_{DD}
$V_{IL,R}$	Refclk input Low Voltage		0.3	V_{DDIR}
$V_{IH,R}$	Refclk input High Voltage	0.7		V_{DDIR}
$V_{IL,PD}$	Input Signal Low Voltage for PD Inputs and StopB		0.3	V_{DDIPD}
$V_{IH,PD}$	Input Signal High Voltage for PD Inputs and StopB	0.7		V_{DDIPD}
V_{DDIR}	Input Supply Reference for Refclk	1.235	3.465	V
V_{DDIPD}	Input Supply Reference for PD Inputs	1.235	2.625	V

Notes:

- Refclk jitter measured at V_{DDIR} (nom)/2.
- If input modulation is used: input modulation is allowed but not required.
- Capacitance measured at Freq = 1 MHz, DC bias = 0.9V and $V_{AC} < 100$ mV.
- The amount of allowed spreading for any non-triangular modulation is determined by the induced downstream tracking skew, which cannot exceed the skew generated by the specified 0.6% triangular modulation. Typically, the amount of allowed non-triangular modulation is about 0.5%.

Table 14. Device Characteristics

Parameter	Description	Min.	Max.	Unit
t_{CYCLE}	Clock Cycle Time (Commercial temperature)	1.87	3.75	ns
t_{CYCLE}	Clock Cycle Time (Industrial temperature)	2.5	3.75	ns
t_{J}	Cycle-to-Cycle Jitter at Clk/ClkB ^[6]	-	50	ps
t_{STEP}	Phase Aligner Phase Step Size (at Clk/ClkB)	1	-	ps
$t_{\text{ERR,PD}}$	Phase Detector Phase Error for Distributed Loop Measured at PclkM-SynclkN (rising edges) (does not include clock jitter)	-100	100	ps
$t_{\text{ERR,SSC}}$	PLL Output Phase Error when Tracking SSC	-100	100	ps
$V_{\text{X,STOP}}$	Output Voltage during Clk Stop (StopB=0)	1.1	2.0	V
V_{X}	Differential Output Crossing-Point Voltage	1.3	1.8	V
V_{COS}	Output Voltage Swing (p-p single-ended) ^[7]	0.8	1.2	V
V_{OH}	Output High Voltage	-	2.2	V
V_{OL}	Output Low voltage	0.8	-	V
r_{OUT}	Output Dynamic Resistance (at pins) ^[8]	12	50	Ω
I_{OZ}	Output Current during Hi-Z (S0 = 0, S1 = 1)	-	50	μA
$I_{\text{OZ,STOP}}$	Output Current during Clk Stop (StopB = 0)	-	500	μA
DC	Output Duty Cycle over 10,000 Cycles	40	60	% t_{CYCLE}
$t_{\text{DC,ERR}}$	Output Cycle-to-Cycle Duty Cycle Error	-	50	ps
$t_{\text{R}}, t_{\text{F}}$	Output Rise and Fall Times (measured at 20%-80% of output voltage)	150	400	ps
$t_{\text{CR,CF}}$	Difference between Output Rise and Fall Times on the Same Pin of a Single Device (20%-80%)	-	100	ps

Notes:

6. Output Jitter spec measured at $t_{\text{CYCLE}} = 1.87$ ns. (Commercial Temperature)
7. $V_{\text{COS}} = V_{\text{OH}} - V_{\text{OL}}$.
8. $r_{\text{OUT}} = \Delta V_{\text{O}} / \Delta I_{\text{O}}$. This is defined at the output pins.
