DESCRIPTION

The DS2064 is a 65536-bit low power, fully static random access memory organized as 8192 words by eight bits using CMOS technology. The device operates from a single power supply with a voltage input between 4.5V and 5.5V. The chip enable inputs (CE_1 and CE_2) are used for device selection and can be used in order to achieve the minimum standby current mode, which fa-

cilitates both battery operate and battery backup applications. The device provides fast access time of 200 ns and is most suitable for low power applications where battery operation or battery backup for nonvolatility are required. The DS2064 is a JEDEC-standard 8K x 8 SRAM and is pin-compatible with ROM and EPROM of similar density.

NOTES:

1. WE is high for read cycles.
2. $\overline{OE} = V_{IH}$ or V_{IL} . If $\overline{OE} = V_{IH}$ during write cycle, the output buffers remain in a high impedance state.
3. t_{WP} is specified as the logical AND of \overline{CE} and \overline{WE} . t_{WP} is measured from the latter of \overline{CE} or \overline{WE} going low to the earlier of \overline{CE} or \overline{WE} going high.
4. t_{DH} and t_{DS} are measured from the earlier of \overline{CE} or \overline{WE} going high.
5. If the \overline{CE} low transition occurs simultaneously with or latter than the \overline{WE} low transition, the output buffers remain in a high impedance state.
6. If the \overline{CE} high transition occurs prior to or simultaneously with the \overline{WE} high transition, the output buffers remain in a high impedance state.
7. If \overline{WE} is low or the \overline{WE} low transition occurs prior to or simultaneously with the \overline{CE} low transition, the output buffers remain in a high impedance state.
8. If the V_{IH} level of \overline{CE} is 2.0V during the period that V_{CC} voltage is going down from 4.5V to 2.7V, I_{CCS1} current flows.
