DESCRIPTION:

This 20-bit bus-interface flip-flop is built using advanced CMOS

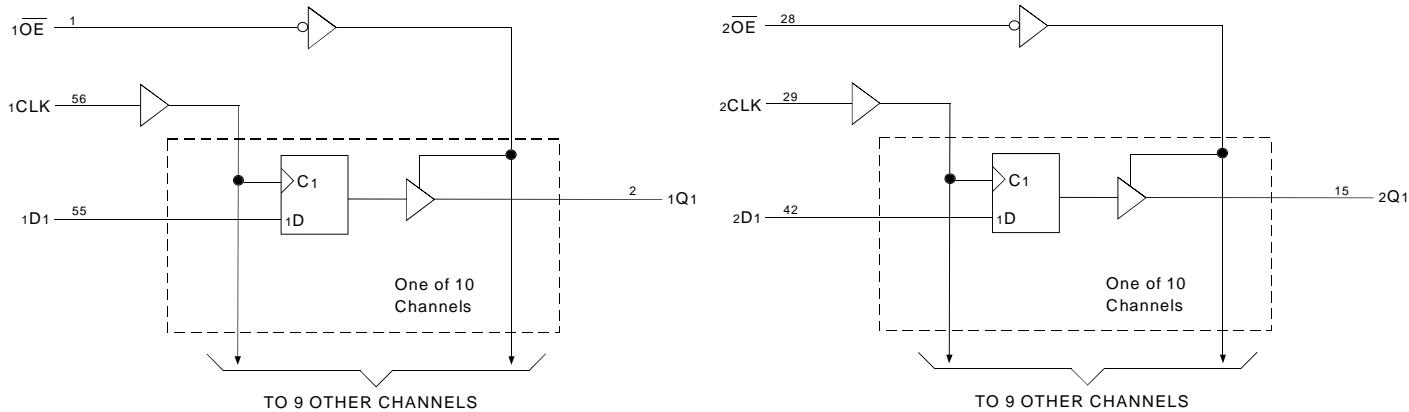

technology. The ALVCH162821 device can be used as two 10-bit flip-flops or one 20-bit flip-flop. The 20-bit flip-flops are edge-triggered D-type flip-flops. On the positive transition of the clock (CLK) input, the device provides true data to the Q outputs.

A buffered output-enable (\overline{OE}) input can be used to place the ten outputs in either a normal logic state (high or low logic levels) or a high-impedance state. In the high impedance state, the outputs neither load nor drive the bus lines significantly. The high-impedance state and increased drive provide the capability to drive bus lines without the need for interface or pullup components. \overline{OE} input does not affect the internal operation of the flip-flops. Old data can be retained or new data can be entered while the outputs are in the high-impedance state.

The ALVCH162821 has series resistors in the device output structure which will significantly reduce line noise when used with light loads. This driver has been designed to drive $\pm 12\text{mA}$ at the designated threshold levels.

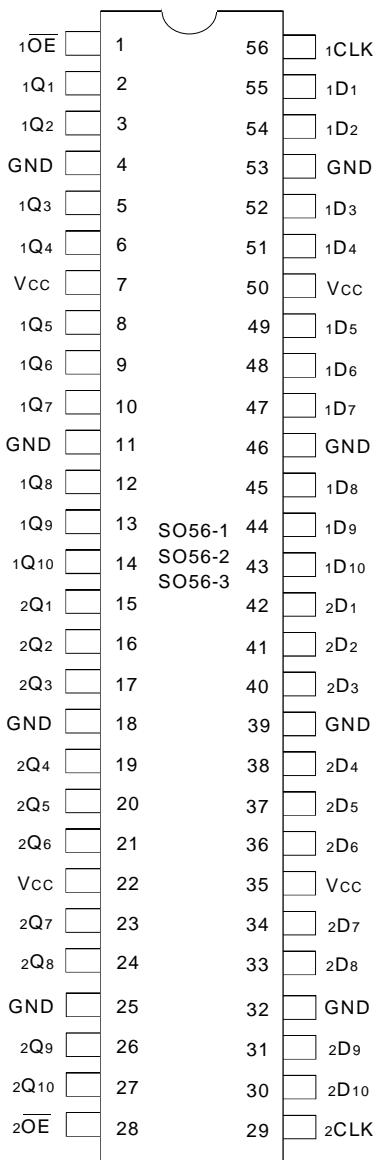

The ALVCH162821 has "bus-hold" which retains the inputs' last state whenever the input goes to a high impedance. This prevents floating inputs and eliminates the need for pull-up/down resistor.
