

## 16-BIT SERIAL TO PARALLEL CONVERTER

### ■ GENERAL DESCRIPTION

The NJU3716 is a 16-bit serial to parallel converter especially apply to MPU outport expander.

The effective outport assignment of MPU is available as the connection between NJU3716 and MPU is required only 4 lines.

Up to 5MHz signal can be input to the serial data input terminal and the data is output from parallel output buffer through serial in parallel out shift register and parallel data latches.

Furthermore, the NJU3716 output the serial data from SO terminal through the shift register, therefore output bit number can increase by cascade connection.

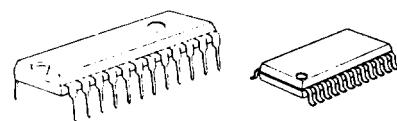

The hysteresis input circuit realized wide noise margin and high drivability output buffer ( 25mA ) can drive LED directly.

### ■ FEATURES

- 16-Bit Serial In Parallel Out
- Cascade Connection
- Hysteresis Input ----- 0.5V typ
- Operating Voltage ----- 5V±10%
- Operating Frequency ----- 5MHz or more
- Output Current ----- 25mA
- C-MOS Technology
- Package Outline ----- SDIP/DMP 24

## ■ FUNCTIONAL DESCRIPTION

### (1) Reset

When the "L" level is input to the CLR terminal, all latches are reset and all parallel conversion output are "L" level.

Normally, the CLR terminal should be "H" level.

### (2) Data Transmission

In the STB terminal is "H" level and input the clock signal to the CLK terminal, the serial data input from DATA terminal shift in the shift register by syncronizing at rising edge of the clock signal.

When the STB terminal change to "L" level, the data in the shift register transfer to the latch.

Even if the STB terminal is "L" level, the input clock signal shift the data in the shift register, therefore, the clock signal control is needed.

### (3) Cascade Connection

The serial data input from DATA terminal output from the S0 terminal through internal shift register unrelated the CLR and STB status.

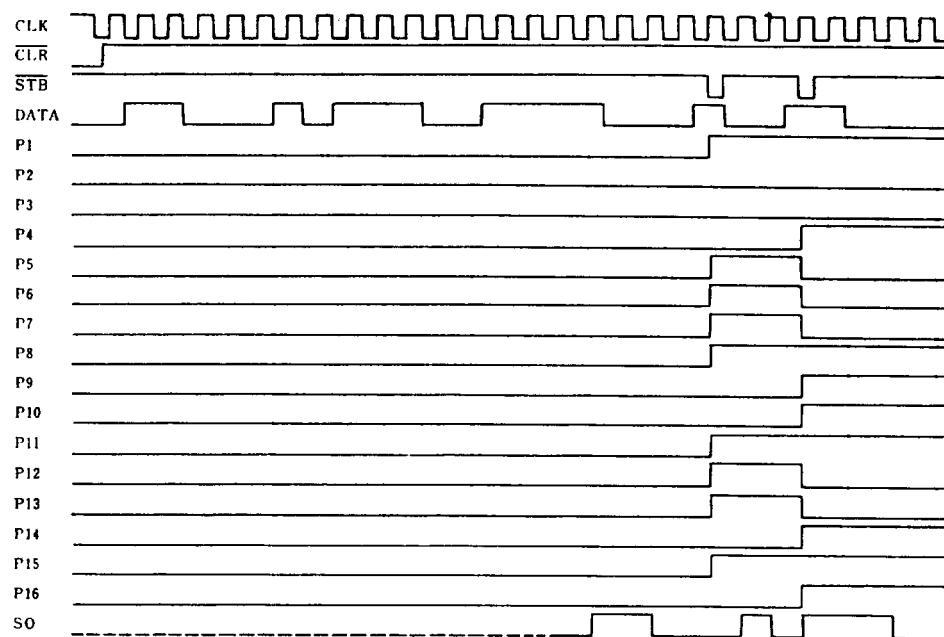

Furthermore, the 4 input terminals have a hysteresis characteristics by using the schmitt trigger structure to protect the noise.

CLK	STB	CLR	OPERATION
X	X	L	All latch are reset (the data in the shift register is no change). All of Parallel convert output are "L".
↑L	H	H	The serial data input from DATA terminal input to the shift register. In this stage, the data in the latch is no change.
L	L	H	The data in the shift register transfer to the latch. And the data in the latch output from parallel output.
↑L			The CLK input in the STB="L" and CLR="H" state, the data shift in the shift register and latched data also change in accordance with the shift register.
