2-Way Multiplexed LCD Drive and Low Cost A/D Converter
Using V/F Techniques with COP8 Microcontrollers

ABSTRACT

This application note is intended to show a general solution for implementing a low cost A/D and a 2-way multiplexed LCD drive using National Semiconductor's COP840C 8-bit microcontroller. The implementation is demonstrated by means of a digital personal scale. Details and function of the weight sensor itself are not covered in this note. Also the algorithms used to calculate the weight from the measured frequency are not included, as they are too specific and depend on the kind of sensor used.

Typical Applications

- Weighing scales
- Sensors with voltage output
- Capacitive or resistive sensors
- All kinds of measuring equipment
- Automotive test and control systems

Features

- 2-way multiplexed LCD drive capability up to 30 segments (4 digit and 2 dot points)
- Precision frequency measurement
- Low current consumption
- Current saving HALT mode
- Additional computing power for application specific tasks

INTRODUCTION

Today's most popular digital scales all have the following characteristics:

They are battery powered and use a LCD to display the weight. Instead of using a discrete A/D-converter, in many cases a V/F converter is used, which converts an output voltage change of the weight sensor to a frequency change. This frequency is measured by a microcontroller and is used to calculate the weight. The advantages of a V/F over an A/D converter are multifold. Only one line from the V/F to the microcontroller is needed, whereas a parallel A/D needs at least 8 lines or even more (National also offers A/Ds with serial output). A V/F can be constructed very simply using National Semiconductor's low cost, precision voltage to frequency converters LM331 or LM331A. Other possibilities are using Op-amps or a 555-timer in astable mode.

V/F-CONVERSION

Hardware

The basic configuration of the scale described in this application note is shown in *Figure 1*.

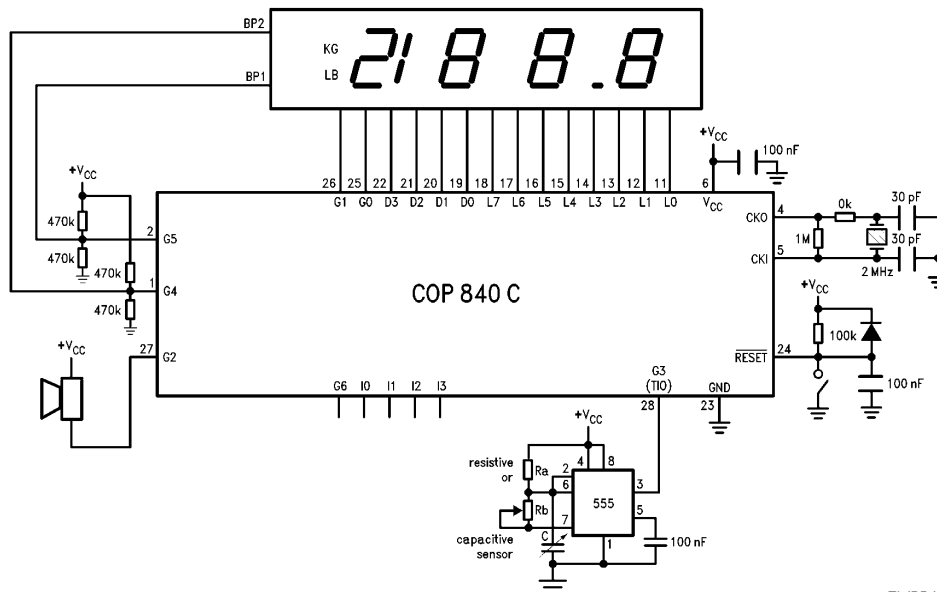

FIGURE 1. System Diagram

TL/DD/10788-1

TRI-STATE® is a registered trademark of National Semiconductor Corporation.

A capacitive or resistive sensor's weight related capacitance or resistance change is transformed by a 555 timer (in astable mode) to a change of frequency. The output frequency f is determined by the formula:

$$f = 1.44 / ((R_a + 2R_b) * C)$$

The output high time is given by:

$$t_1 = 0.693 * (R_a + R_b) * C$$

The output low time is given by:

$$t_2 = 0.693 * R_b * C$$

This frequency is measured using the COP800 16-bit timer in the "input capture" mode. After calculation, the weight is displayed on a 2-way multiplexed LCD. Using this configuration a complete scale can be built using only two ICs and a few external passive components.

For more information on V/F converters generally used with voltage output sensors, refer to the literature listed in the reference section.

Frequency Measurement

The COP 16-bit timer is ideally suited for precise frequency measurements with minimum software overhead. This timer has three programmable operating modes, of which the "input capture" mode is used for the frequency measurement. Allocated with the timer is a 16-bit "autoload/capture register". The G3-I/O-pin serves as the timer capture input (TIO). In the "input capture" mode the timer is decremented with the instruction cycle frequency (t_c). Each positive going edge at TIO (also neg. edge programmable) causes the timer value to be copied automatically to the autoload/capture register without stopping the timer or destroying its

contents. The "timer pending" flag (TPND) in the PSW-register is set to indicate a capture has occurred, and if the timer-interrupt is enabled, an interrupt is generated. The frequency measurement routine listed below executes the following operations (refer to the RAM/register definition file listed at the beginning for symbolic names used in the routines):

The timer is preset with FFFF Hex and is started by setting the TRUN bit, after which the software checks the TPND-flag in a loop (timer interrupt is disabled). When the TPND flag is set the first time, the contents of the capture register is saved in RAM locations STALO and STAHI (start value). The TPND pending flag now must be reset by the software. Then, another 255 positive going edges are counted (equal to 255 pulses) before the capture register is saved in RAM locations ENDLO, ENDHI (end value). The shortest time period that can be measured depends on the number of instruction cycles needed to save the capture register, because with the next positive going edge on TIO the contents of the capture register is overwritten (worst case is 18 instruction cycles, which equals a max. frequency of 55.5 kHz at $t_c = 1 \mu s$).

The end-value is subtracted from the start-value and the result is restored in RAM locations STALO, STAHI. This value can then be used to calculate the time period of the frequency applied to TIO (G3) by multiplying it with the t_c -time and dividing the result by the number of pulses measured ($N = 255$).

$$T = (\text{startvalue} - \text{endvalue}) * t_c / N$$

TL/DD/10788-6

2-WAY MULTIPLEXED LCD DRIVE

Today a wide variety of LCDs, ranging from static to multiplex rates of 1:64 are available on the market. The multiplex rate of a LCD can be determined by the number of its backplanes (segment-common plate). The higher the multiplex rate the more individual segments can be controlled using only one line. e.g. a static LCD only has one backplane; only one segment can be controlled with one line. A two-way multiplexed LCD has two backplanes and two segments can be controlled with one line, etc.

Common to all LCDs is the fact that the drive voltage applied to the backplane(s) and segments has to be alternating. DC-components higher than 100 mV can cause electrochemical reactions (refer to manufacturer's spec), which reduce reliability and lifetime of the display.

If the multiplex ratio of the LCD is N and the amount of available outputs is M, the number of segments that can be driven is:

$$S = (M - N) * N$$

So the maximum number of a 2-way mux LCD's segments that can be driven with a COP800 in 28-pin package (if all outputs can be used to drive the LCD) is:

$$S = (18 - 2) * 2 = 32$$

During one LCD refresh cycle tx (typical values for $1/t_x = f_x$ are in the range 30 Hz ... 60 Hz), three different voltages levels: Vop, $0.5 * V_{op}$ and 0V have to be generated. The "off" voltage across a segment is not 0V as with static LCDs and also the "on" voltage is not Vop, but only a fraction of it. The ratio of "on" to "off" r.m.s.-voltage (discrimination) is determined by the multiplex ratio and the number of voltage levels involved. The most desirable discrimination ratio is one that maximizes the ratio of V_{ON} to V_{OFF} , allowing the maximum voltage difference between activated and non-activated states. In general the maximum achievable ratio for any particular value of N is given by:

$$(V_{ON}/V_{OFF})_{max} = SQR((SQR(N) + 1)/(SQR(N) - 1))$$

SQR = square root

Using this formula the maximum achievable discrimination ratio for a 2-way multiplex LCD is 2.41, however, it is also possible to order a customized display with a smaller ratio. For ease of operation, most LCD drivers use equal voltage steps (0V, $0.5 * V_{op}$, Vop). Thus a discrimination ratio of 2.24 is achieved. When using the COP800 to drive a 2-way multiplexed LCD the only external hardware required to achieve the three voltage steps are 4 equal resistors that form two voltage dividers—one for each backplane

(Figure 1). The procedure is to set G4 and G5 to "0" for 0V, to HI-Z (TRI-STATE®) for $0.5 * V_{op}$ and to "1" in order to establish Vop at the backplane electrodes.

With the COP800 each I/O pin can be set individually to TRI-STATE, "1" or "0", so this procedure can be implemented very easily.

The current consumption of typical LCDs is in the range of $3 \mu A$ to $4 \mu A$ (at $V_{op} = 4.5V$, refresh rate 60 Hz) per square centimeter of activated area. Thus the backplane and segment terminals can be treated as HI-Z loads. At high refresh rates the LCD's current consumption increases dramatically, which is the reason why many LCD manufacturers recommend not using a refresh frequency higher than 60 Hz.

Timing Considerations

As shown in Figures 2 and 3, one LCD refresh cycle tx is subdivided into four equally distant time sections ta, tb, tc and td during which the backplane and segment terminals have to be updated in order to switch a specific segment on or off. Considering a refresh frequency of 50 Hz ($t_x = 20$ ms) ta, tb, tc and td are equal to 5 ms; a COP800 running from an external clock of 2 MHz has an internal instruction cycle time of $5 \mu s$ and a typical current consumption of less than $350 \mu A$ (at $V_{CC} = 3V$ and room temperature), thus meeting both the requirements of low current consumption and additional computing power between LCD refreshes.

The timing is done using the COP800's 16-bit timer in the PWM autoloader mode. The timer and the assigned 16-bit autoloader register are preset with proper values. By setting the TRUN-flag in the CNTRL-register the timer is decremented each instruction cycle. A flag (TPND) is set at underflow and the timer is automatically reloaded with the value stored in the autoloader-register. Timer underflow can also be programmed to generate an interrupt.

Segment Control

Figure 2 shows the voltage-waveforms applied to the two backplane-electrodes (a) and the waveform at a segment-electrode (b), which is needed to switch segment A on and segment B off. The resulting voltage over the segments (c and d) is achieved by subtracting waveform (b) from BP1 (segment A) and waveform (b) from BP2 (segment B).

Figure 3 shows the four different waveforms which must be generated to meet all possible combinations of two segments connected to the same driving terminal (off-off, on-off, off-on, on-on).

Figure 4 shows the internal segment and backplane connections for a typical 2-way mux LCD.

LCD Drive Subroutine

The LCD drive subroutine DISPL converts a 16-bit binary value to a 24-bit BCD-value for easier display data fetch. The drive subroutine itself is built up of a main routine doing the backplane refresh and 7 subroutines (SEG0, SEG1, SEG2, SEG3, SEGOUT, TTPND, DISPD). The subroutines SEG0 to SEG4 are used to get the LCD segment data from a look-up table in ROM for time phases t_a , t_b , t_c and t_d respectively. Subroutine SEGOUT writes the segment data for each time phase to the corresponding output ports. One time phase takes 5 ms, giving a total refresh cycle time of 20 ms (50 Hz). The exact timing is done by using the COP800 16-bit timer in the PWM autoloading mode. In that mode the timer is reloaded with the value stored in the autoloading register on every timer underflow. At the same time the timer pending flag is set. The subroutine TTPND checks this flag in a loop. If the timer pending flag is set, this subroutine resets it and returns to the calling program. Thus a 5 ms time delay is created before the segment and backplane data for the next time phase is written to the output ports. Finally the subroutine DISPD switches off the LCD by setting the backplane and segment connections to "0". In this digital scale application a frequency measurement is made while the LCD is off. Then the weight is calculated from this frequency and is displayed for 10s. After this 10s the LCD is switched off again and the COP800 is programmed to enter the current saving HALT mode ($I_{DD} < 10 \mu A$). A new weight cycle on the digital scale is initiated by pressing a push button, which causes a reset of the microcontroller.

CONCLUSIONS

National Semiconductor's COP800 Microcontroller family is ideally suited for use with V/F converters and 2-way multiplexed LCDs, as they offer features, which are essential for these types of applications. The high resolution, 3-mode programmable 16-bit timer allows precise frequency measurement in the input capture mode with minimum software overhead. The timer's PWM autoreload mode offers an easy way to implement a precise timebase for the LCD refresh. The COP800's programmable I/O ports provide flexibility in driving 2-way multiplexed LCDs directly. The COP800 family, fabricated using M2CMOS technology, offers both low voltage (min V_{CC} of 2.5V) and low current drain.

LIFE SUPPORT POLICY

NATIONAL'S PRODUCTS ARE NOT AUTHORIZED FOR USE AS CRITICAL COMPONENTS IN LIFE SUPPORT DEVICES OR SYSTEMS WITHOUT THE EXPRESS WRITTEN APPROVAL OF THE PRESIDENT OF NATIONAL SEMICONDUCTOR CORPORATION. As used herein:

1. Life support devices or systems are devices or systems which, (a) are intended for surgical implant into the body, or (b) support or sustain life, and whose failure to perform, when properly used in accordance with instructions for use provided in the labeling, can be reasonably expected to result in a significant injury to the user.
2. A critical component is any component of a life support device or system whose failure to perform can be reasonably expected to cause the failure of the life support device or system, or to affect its safety or effectiveness.
