

#### LMC6462 Dual/LMC6464 Quad Micropower, Rail-to-Rail Input and Output CMOS Operational Amplifier

#### **General Description**

The LMC6462/4 is a micropower version of the popular LMC6482/4, combining Rail-to-Rail Input and Output Range with very low power consumption.

The LMC6462/4 provides an input common-mode voltage range that exceeds both rails. The rail-to-rail output swing of the amplifier, guaranteed for loads down to 25 k $\Omega$ , assures maximum dynamic sigal range. This rail-to-rail performance of the amplifier, combined with its high voltage gain makes it unique among rail-to-rail amplifiers. The LMC6462/4 is an excellent upgrade for circuits using limited common-mode range amplifiers.

The LMC6462/4, with guaranteed specifications at 3V and 5V, is especially well-suited for low voltage applications. A quiescent power consumption of 60  $\mu$ W per amplifier (at Vs = 3V) can extend the useful life of battery operated systems. The amplifier's 150 fA input current, low offset voltage of 0.25 mV, and 85 dB CMRR maintain accuracy in battery-powered systems.

#### Features (Typical unless otherwise noted)

- Ultra Low Supply Current
- 20 μA/Amplifier
- Guaranteed Characteristics at 3V and 5V
- Rail-to-Rail Input Common-Mode Voltage Range
- Rail-to-Rail Output Swing (within 10 mV of rail, V<sub>S</sub> = 5V and R<sub>L</sub> = 25 kΩ)
- Low Input Current

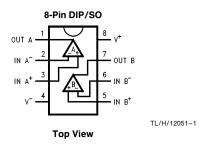

150 fA 0.25 mV

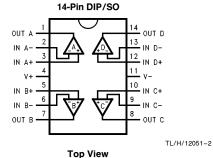

■ Low Input Offset Voltage

#### **Applications**

- Battery Operated Circuits
- Transducer Interface Circuits
- Portable Communication Devices
- Medical Applications
- Battery Monitoring

#### **Connection Diagrams**

#### **Ordering Information**

Note 1: Absolute Maximum Ratings indicate limits beyond which damage to the device may occur. Operating Ratings indicate conditions for which the device is intended to be functional, but specific performance is not guaranteed. For guaranteed specifications and the test conditions, see the Electrical Characteristics.

Note 2: Human body model, 1.5  $k\Omega$  in series with 100 pF. All pins rated per method 3015.6 of MIL-STD-883. This is a class 2 device rating.

Note 3: Applies to both single supply and split-supply operation. Continuous short circuit operation at elevated ambient temperature can result in exceeding the maximum allowed junction temperature of 150°C. Output currents in excess of ±30 mA over long term may adversely affect reliability.

Note 4: The maximum power dissipation is a function of  $T_{J(max)}$ ,  $\theta_{JA}$ , and  $T_A$ . The maximum allowable power dissipation at any ambient temperature is  $P_D = (T_{J(max)} - T_A)/\theta_{JA}$ . All numbers apply for packages soldered directly into a PC board.

Note 5: Typical Values represent the most likely parametric norm.

Note 6: All limits are guaranteed by testing or statistical analysis.

Note 7: V  $^+$  = 15V, V<sub>CM</sub> = 7.5V and R<sub>L</sub> connected to 7.5V. For Sourcing tests, 7.5V  $\leq$  V<sub>O</sub>  $\leq$  11.5V. For Sinking tests, 3.5V  $\leq$  V<sub>O</sub>  $\leq$  7.5V.

Note 8: Do not short circuit output to V+, when V+ is greater than 13V or reliability will be adversely affected.

Note 9: V<sup>+</sup> = 15V. Connected as Voltage Follower with 10V step input. Number specified is the slower of either the positive or negative slew rates.

Note 10: Input referred, V $^+$  = 15V and R $_L$  = 100 k $\Omega$  connected to 7.5V. Each amp excited in turn with 1 kHz to produce V $_O$  = 12 V $_{PP}$ .

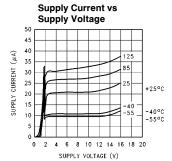

Note 11: Connected as Voltage Follower with 2V step input. Number specified is the slower of either the positive or negative slew rates.

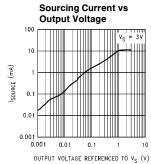

Note 12: Limiting input pin current is only necessary for input voltages that exceed absolute maximum input voltage ratings.

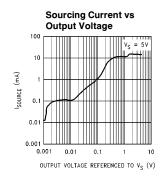

Note 13: Guaranteed limits are dictated by tester limitations and not device performance. Actual performance is reflected in the typical value.

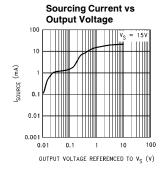

Note 14: For guaranteed Military Temperature Range parameters see RETSMC6462/4X.

#### **Application Information**

# 1.0 Input Common-Mode Voltage Range

The LMC6462/4 has a rail-to-rail input common-mode voltage range. *Figure 1* shows an input voltage exceeding both supplies with no resulting phase inversion on the output.

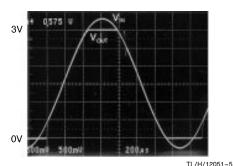

FIGURE 1. An Input Voltage Signal Exceeds the LMC6462/4 Power Supply Voltage with No Output Phase Inversion

The absolute maximum input voltage at V  $^+=3$ V is 300 mV beyond either supply rail at room temperature. Voltages greatly exceeding this absolute maximum rating, as in Figure 2, can cause excessive current to flow in or out of the input pins, possibly affecting reliability. The input current can be externally limited to  $\pm 5$  mA, with an input resistor, as shown in Figure 3.

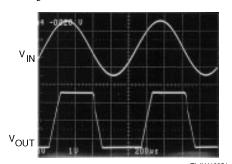

FIGURE 2. A ±7.5V Input Signal Greatly Exceeds the 3V Supply in *Figure 3* Causing
No Phase Inversion Due to R<sub>1</sub>

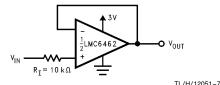

FIGURE 3. Input Current Protection for Voltages
Exceeding the Supply Voltage

#### 2.0 Rail-to-Rail Output

The approximated output resistance of the LMC6462/4 is 180 $\Omega$  sourcing, and 130 $\Omega$  sinking at V<sub>S</sub> = 3V, and 110 $\Omega$  sourcing and 83 $\Omega$  sinking at V<sub>S</sub> = 5V. The maximum output swing can be estimated as a function of load using the calculated output resistance.

#### 3.0 Capacitive Load Tolerance

The LMC6462/4 can typically drive a 200 pF load with  $V_S=5V$  at unity gain without oscillating. The unity gain follower is the most sensitive configuration to capacitive load. Direct capacitive loading reduces the phase margin of op-amps. The combination of the op-amp's output impedance and the capacitive load induces phase lag. This results in either an underdamped pulse response or oscillation.

Capacitive load compensation can be accomplished using resistive isolation as shown in *Figure 4*. If there is a resistive component of the load in parallel to the capacitive component, the isolation resistor and the resistive load create a voltage divider at the output. This introduces a DC error at the output.

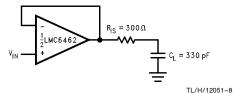

FIGURE 4. Resistive Isolation of a 300 pF Capacitive Load

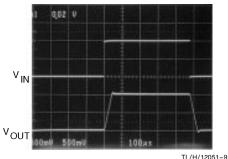

FIGURE 5. Pulse Response of the LMC6462 Circuit Shown in Figure 4

Figure 5 displays the pulse response of the LMC6462/4 circuit in Figure 4.

Another circuit, shown in *Figure 6*, is also used to indirectly drive capacitive loads. This circuit is an improvement to the circuit shown in *Figure 4* because it provides DC accuracy as well as AC stability. R1 and C1 serve to counteract the loss of phase margin by feeding the high frequency component of the output signal back to the amplifiers inverting input, thereby preserving phase margin in the overall feedback loop. The values of R1 and C1 should be experimentally determined by the system designer for the desired pulse response. Increased capacitive drive is possible by increasing the value of the capacitor in the feedback loop.

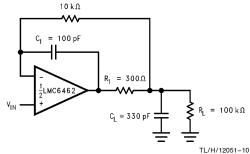

FIGURE 6. LMC6462 Non-Inverting Amplifier, Compensated to Handle a 300 pF Capacitive and 100 kΩ Resistive Load

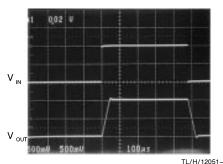

FIGURE 7. Pulse Response of LMC6462 Circuit in Figure 6

The pulse response of the circuit shown in Figure 6 is shown in Figure 7.

# 4.0 Compensating for Input Capacitance

It is quite common to use large values of feedback resistance with amplifiers that have ultra-low input current, like the LMC6462/4. Large feedback resistors can react with small values of input capacitance due to transducers, photodiodes, and circuits board parasitics to reduce phase margins

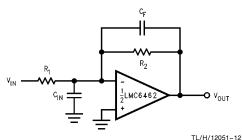

FIGURE 8. Canceling the Effect of Input Capacitance

The effect of input capacitance can be compensated for by adding a feedback capacitor. The feedback capacitor (as in Figure 8 ),  $C_F$ , is first estimated by:

$$\frac{1}{2\pi R_1 \; C_{IN}} \geq \frac{1}{2\pi R_2 \; C_F}$$

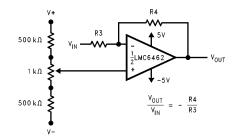

$$\begin{array}{c} \text{or} \\ \text{R}_1 \ \text{C}_{IN} \leq \text{R}_2 \ \text{C}_F \end{array}$$

which typically provides significant overcompensation.

Printed circuit board stray capacitance may be larger or smaller than that of a breadboard, so the actual optimum value for  $C_{\text{F}}$  may be different. The values of  $C_{\text{F}}$  should be checked on the actual circuit. (Refer to the LMC660 quad CMOS amplifier data sheet for a more detailed discussion.)

#### 5.0 Offset Voltage Adjustment

Offset voltage adjustment circuits are illustrated in Figures 9 and 10. Large value resistances and potentiometers are used to reduce power consumption while providing typically  $\pm 2.5$  mV of adjustment range, referred to the input, for both configurations with V<sub>S</sub>  $=\,\pm\,5$ V.

#### 6.0 Spice Macromodel

A Spice macromodel is available for the LMC6462/4. This model includes a simulation of:

- Input common-mode voltage range
- Frequency and transient response
- GBW dependence on loading conditions
- Quiescent and dynamic supply current
- · Output swing dependence on loading conditions

and many more characteristics as listed on the macromodel disk.  $% \label{eq:macromodel}$ 

Contact the National Semiconductor Customer Response Center to obtain an operational amplifier Spice model library

# 7.0 Printed-Circuit-Board Layout for High-Impedance Work

It is generally recognized that any circuit which must operate with less than 1000 pA of leakage current requires special layout of the PC board. When one wishes to take advantage of the ultra-low input current of the LMC6462/4, typically 150 fA, it is essential to have an excellent layout. Fortunately, the techniques of obtaining low leakages are quite simple. First, the user must not ignore the surface leakage of the PC board, even though it may sometimes appear acceptably low, because under conditions of high humidity or dust or contamination, the surface leakage will be appreciable

To minimize the effect of any surface leakage, lay out a ring of foil completely surrounding the LMC6462's inputs and the terminals of capacitors, diodes, conductors, resistors, relay terminals, etc. connected to the op-amp's inputs, as in Figure 11. To have a significant effect, guard rings should be placed in both the top and bottom of the PC board. This PC foil must then be connected to a voltage which is at the same voltage as the amplifier inputs, since no leakage current can flow between two points at the same potential. For example, a PC board trace-to-pad resistance of  $10^{12}\Omega$ , which is normally considered a very large resistance, could leak 5 pA if the trace were a 5V bus adjacent to the pad of the input. This would cause a 30 times degradation from the LMC6462/4's actual performance. However, if a guard ring is held within 5 mV of the inputs, then even a resistance of  $10^{11}\Omega$  would cause only 0.05 pA of leakage current. See Figures 12a, 12b and 12c for typical connections of guard rings for standard op-amp configurations.

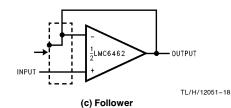

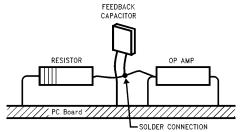

FIGURE 12. Typical Connections of Guard Rings

The designer should be aware that when it is inappropriate to lay out a PC board for the sake of just a few circuits, there is another technique which is even better than a guard ring on a PC board: Don't insert the amplifier's input pin into the board at all, but bend it up in the air and use only air as an insulator. Air is an excellent insulator. In this case you may have to forego some of the advantages of PC board construction, but the advantages are sometimes well worth the effort of using point-to-point up-in-the-air wiring. See Figure 13.

#### **8.0 Instrumentation Circuits**

The LMC6464 has the high input impedance, large common-mode range and high CMRR needed for designing instrumentation circuits. Instrumentation circuits designed with the LMC6464 can reject a larger range of commonde signals than most in-amps. This makes instrumentation circuits designed with the LMC6464 an excellent choice for noisy or industrial environments. Other applications that

benefit from these features include analytic medical instruments, magnetic field detectors, gas detectors, and siliconbased transducers.

A small valued potentiometer is used in series with Rg to set the differential gain of the three op-amp instrumentation circuit in *Figure 14*. This combination is used instead of one large valued potentiometer to increase gain trim accuracy and reduce error due to vibration.

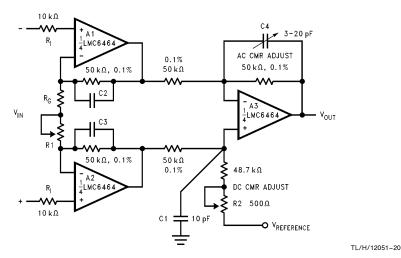

FIGURE 14. Low Power Three Op-Amp Instrumentation Amplifier

A two op-amp instrumentation amplifier designed for a gain of 100 is shown in *Figure 15*. Low sensitivity trimming is made for offset voltage, CMRR and gain. Low cost and low power consumption are the main advantages of this two opamp circuit.

Higher frequency and larger common-mode range applications are best facilitated by a three op-amp instrumentation amplifier.

#### **Typical Single-Supply Applications**

#### TRANSDUCER INTERFACE CIRCUITS

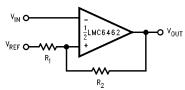

TL/H/12051-22

#### FIGURE 16. Photo Detector Circuit

Photocells can be used in portable light measuring instruments. The LMC6462, which can be operated off a battery, is an excellent choice for this circuit because of its very low input current and offset voltage.

#### LMC6462 AS A COMPARATOR

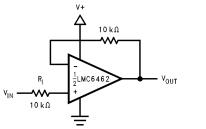

TL/H/12051-23

#### FIGURE 17. Comparator with Hysteresis

Figure 17 shows the application of the LMC6462 as a comparator. The hysteresis is determined by the ratio of the two resistors. The LMC6462 can thus be used as a micropower comparator, in applications where the quiescent current is an important parameter.

#### HALF-WAVE AND FULL-WAVE RECTIFIERS

#### FIGURE 20. Precision Current Source

The output current IOUT is given by:

$$I_{OUT} = \left(\frac{V^+ - V_{IN}}{R}\right)$$

#### **OSCILLATORS**

TL/H/12051-27

FIGURE 21. 1 Hz Square-Wave Oscillator

For single supply 5V operation, the output of the circuit will swing from 0V to 5V. The voltage divider set up  $\rm R_2,\,R_3$  and  $\rm R_4$  will cause the non-inverting input of the LMC6462 to move from 1.67V (1/3 of 5V) to 3.33V (2/3 of 5V). This voltage behaves as the threshold voltage.

 $R_1$  and  $C_1$  determine the time constant of the circuit. The frequency of oscillation,  $f_{OSC}$  is  $\left(\frac{1}{2\Delta t}\right)$ , where  $\Delta t$  is the time

the amplifier input takes to move from 1.67V to 3.33V. The calculations are shown below.

1.67 = 5 
$$\left(1 - e^{-\frac{t_1}{7}}\right)$$
  
where  $\tau$  = RC = 0.68 seconds  
 $\rightarrow$   $t_1$  = 0.27 seconds.  
and  
3.33 = 5  $\left(1 - e^{-\frac{t_2}{7}}\right)$   
 $\rightarrow$   $t_2$  = 0.75 seconds  
Then,  $f_{OSC} = \left(\frac{1}{2\Delta t}\right)$   
=  $\frac{1}{2(0.75 - 0.27)}$   
= 1 Hz

#### **LOW FREQUENCY NULL**

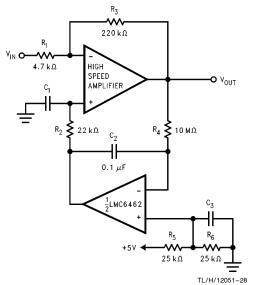

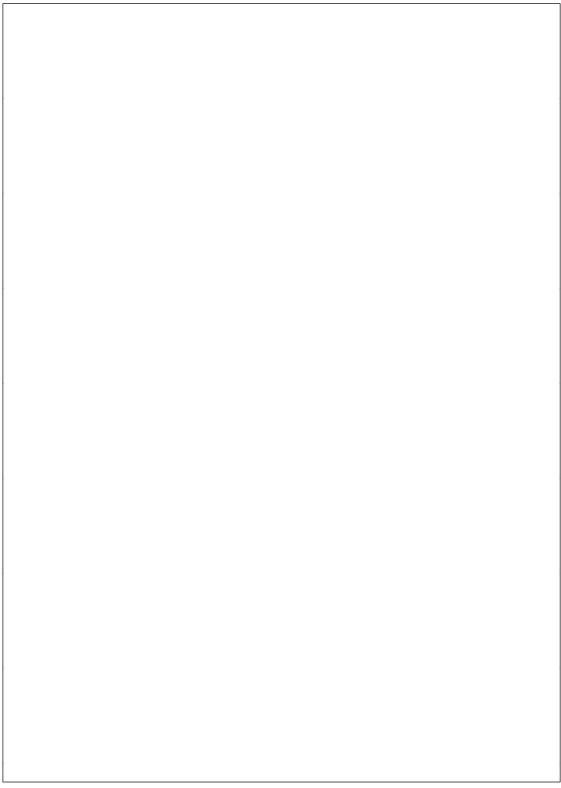

FIGURE 22. High Gain Amplifier with Low Frequency Null

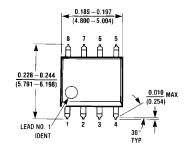

Output offset voltage is the error introduced in the output voltage due to the inherent input offset voltage  $V_{\mbox{OS}}$ , of an amplifier.

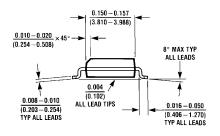

Output Offset Voltage = (Input Offset Voltage) (Gain)

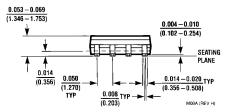

In the above configuration, the resistors  $R_5$  and  $R_6$  determine the nominal voltage around which the input signal,  $V_{IN}$  should be symmetrical. The high frequency component of the input signal  $V_{IN}$  will be unaffected while the low frequency component will be nulled since the DC level of the output will be the input offset voltage of the LMC6462 plus the bias voltage. This implies that the output offset voltage due to the top amplifier will be eliminated.
