DESCRIPTION

This circuit consists of two independent, high gain, internally frequency compensated which were designed specifically for automotive and industrial control system. It operates from a single power supply over a wide range of voltages. The low power supply drain is independent of the magnitude of the power supply voltage.

Application areas include transducer amplifiers, dc gain blocks and all the conventional op-amp circuits which now can be more easily implemented in single power supply systems. For example, these circuits can be directly supplied with off the standard + 5V which is used in logic systems and will easily provide the required interface electronics without requiring any additional power supply.

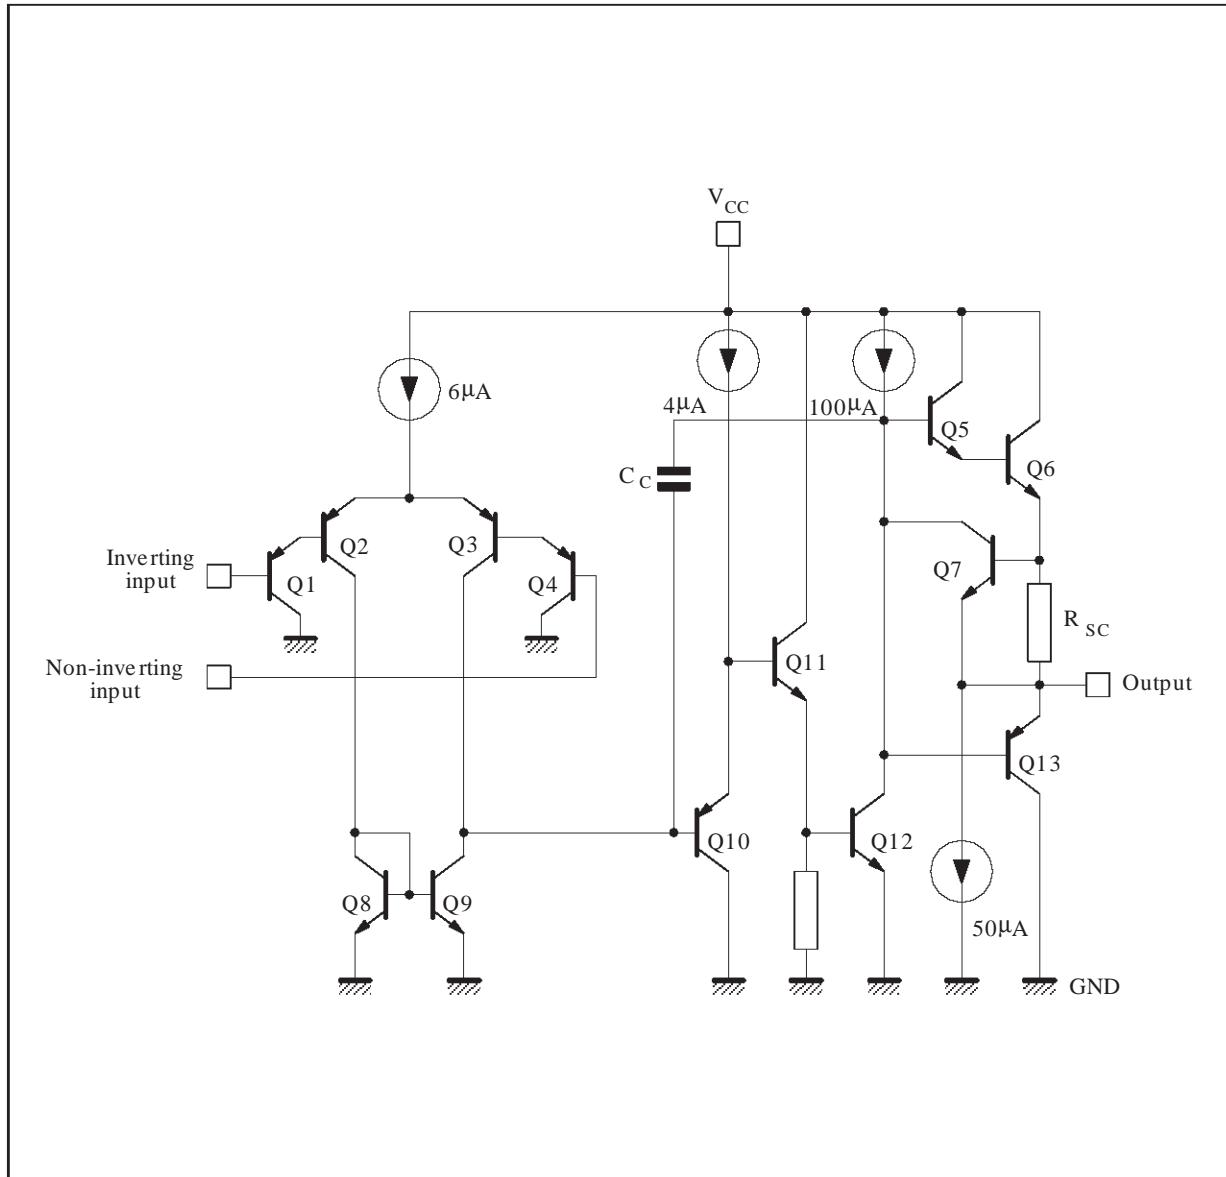

In the linear mode the input common-mode voltage range includes ground and the output voltage can also swing to ground, even though operated from only a single power supply voltage.

- Notes :
- This input current only exist when the voltage at any of the input leads is driven negative. It is due to the collector-base junction of the input PNP transistor becoming forward biased and thereby acting as input diode clamps. In addition to this diode action, there is also NPN parasitic action on the IC chip. This transistor action can cause the output voltages of the Op-amps to go to the V_{CC} voltage level (or to ground for a large overdrive) for the time duration that an input is driven negative. This is not destructive and normal output will set up again for input voltage higher than -0.3V .
 - Short-circuits from the output to V_{CC} can cause excessive heating if $V_{CC}^+ > 15\text{V}$. The maximum output current is approximatively 40mA independent of the magnitude of V_{CC} . Destructive dissipation can result from simultaneous short-circuits on all amplifiers.
 - $V_o = 1.4\text{V}$, $R_s = 0\Omega$, $5\text{V} < V_{CC}^+ < 30\text{V}$, $0 < V_{ic} < V_{CC}^+ - 1.5\text{V}$.
 - The direction of the input current is out of the IC. This current is essentially constant, independent of the state of the output so no loading change exists on the input lines.
 - Due to the proximity of external components insure that coupling is not originating via stray capacitance between these external parts. This typically can be detected as this type of capacitance increases at higher frequencies.
 - The input common-mode voltage of either input signal voltage should not be allowed to go negative by more than 0.3V . The upper end of the common-mode voltage range is $V_{CC}^+ - 1.5\text{V}$. But either or both inputs can go to $+32\text{V}$ without damage.
