

## 8K/16K 1.8V CMOS Serial EEPROM

### FEATURES

- Single supply with programming operation down to 1.8V
- Low power CMOS technology
  - 1 mA active current typical
  - 5  $\mu$ A standby current (typical) at 3.0V
- ORG pin selectable memory configuration  
1024 x 8 or 512 x 16 bit organization (93LAA6)  
2048 x 8 or 1024 x 16 bit organization (93AA86)
- Self-timed ERASE and WRITE cycles (including auto-erase)
- Automatic ERAL before WRAL
- Power on/off data protection circuitry
- Industry standard 3-wire serial I/O
- Device status signal during ERASE/WRITE cycles
- Sequential READ function
- 10,000,000 ERASE/WRITE cycles **guaranteed**
- Data retention > 200 years
- 8-pin PDIP/SOIC package
- Temperature ranges available:
  - Commercial (C): 0°C to +70°C

### DESCRIPTION

The Microchip Technology Inc. 93AA76/86 are 8K and 16K low voltage serial Electrically Erasable PROMs. The device memory is configured as x8 or x16 bits depending on the ORG pin setup. Advanced CMOS technology makes these devices ideal for low power non-volatile memory applications. These devices also have a Program Enable (PE) pin to allow the user to write protect the entire contents of the memory array. The 93AA76/86 is available in standard 8-pin DIP and 8-pin surface mount SOIC packages.

### PIN CONFIGURATION

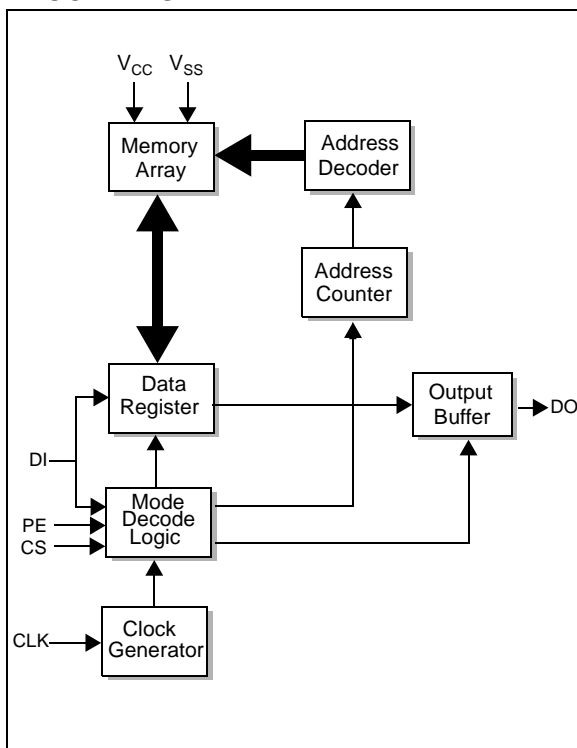

#### DIP Package

## 1.0 ELECTRICAL CHARACTERISTICS

### Maximum Ratings\*

V<sub>CC</sub> ..... 7.0V  
 All inputs and outputs w.r.t. V<sub>SS</sub> .... -0.6V to V<sub>CC</sub> +1.0V  
 Storage temperature ..... -65°C to +150°C  
 Ambient temp. with power applied ..... -65°C to +125°C  
 Soldering temperature of leads (10 seconds) .. +300°C  
 ESD protection on all pins ..... 4 kV

\*Notice: Stresses above those listed under "Maximum ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at those or any other conditions above those indicated in the operational listings of this specification is not implied. Exposure to maximum rating conditions for extended periods may affect device reliability

### AC Test Conditions

Input Pulse Levels ..... 0.4V to 2.4V  
 Output Reference Levels ..... 0.8V and 2.0V

PIN FUNCTION TABLE	
Name	Function
CS	Chip Select
CLK	Serial Data Clock
DI	Serial Data Input
DO	Serial Data Output
V <sub>SS</sub>	Ground
ORG	Memory Configuration
PE	Program Enable
V <sub>CC</sub>	Power Supply

## 2.0 PIN DESCRIPTIONS

### 2.1 Chip Select (CS)

A HIGH level selects the device. A LOW level deselects the device and forces it into standby mode. However, a programming cycle which is already initiated will be completed, regardless of the CS input signal. If CS is brought LOW during a program cycle, the device will go into standby mode as soon as the programming cycle is completed.

CS must be LOW for 250 ns minimum (T<sub>CSL</sub>) between consecutive instructions. If CS is LOW, the internal control logic is held in a RESET status.

### 2.2 Serial Clock (CLK)

The Serial Clock is used to synchronize the communication between a master device and the 93AA76/86. Opcode, address, and data bits are clocked in on the positive edge of CLK. Data bits are also clocked out on the positive edge of CLK.

CLK can be stopped anywhere in the transmission sequence (at HIGH or LOW level) and can be continued anytime with respect to clock HIGH time (T<sub>CKH</sub>) and clock LOW time (T<sub>CKL</sub>). This gives the controlling master freedom in preparing opcode, address, and data.

CLK is a "Don't Care" if CS is LOW (device deselected). If CS is HIGH, but START condition has not been detected, any number of clock cycles can be received by the device without changing its status (i.e., waiting for START condition).

CLK cycles are not required during the self-timed WRITE (i.e., auto ERASE/WRITE) cycle.

After detection of a start condition the specified number of clock cycles (respectively LOW to HIGH transitions of CLK) must be provided. These clock cycles are required to clock in all opcode, address, and data bits before an instruction is executed (see Table 2-1 through Table 2-4 for more details). CLK and DI then become don't care inputs waiting for a new start condition to be detected.

**Note:** CS must go LOW between consecutive instructions, except when performing a sequential read (Refer to Section 4.1 for more detail on sequential reads).

### 2.3 Data In (DI)

Data In is used to clock in a START bit, opcode, address, and data synchronously with the CLK input.

### 2.4 Data Out (DO)

Data Out is used in the READ mode to output data synchronously with the CLK input (T<sub>PD</sub> after the positive edge of CLK).

This pin also provides READY/ $\overline{\text{BUSY}}$  status information during ERASE and WRITE cycles. READY/ $\overline{\text{BUSY}}$  status information is available when CS is high. It will be displayed until the next start bit occurs as long as CS stays high.

### 2.5 Organization (ORG)

When ORG is connected to V<sub>CC</sub>, the x16 memory organization is selected. When ORG is tied to V<sub>SS</sub>, the x8 memory organization is selected. There is an internal pull-up resistor on the ORG pin that will select x16 organization when left unconnected.

### 2.6 Program Enable (PE)

This pin allows the user to enable or disable the ability to write data to the memory array. If the PE pin is floated or tied to V<sub>CC</sub>, the device can be programmed. If the PE pin is tied to V<sub>SS</sub>, programming will be inhibited. There is an internal pull-up on this device that enables programming if this pin is left floating.

### 3.0 PRINCIPLES OF OPERATION

When the ORG pin is connected to Vcc, the x16 organization is selected. When it is connected to ground, the x8 organization is selected. Instructions, addresses and write data are clocked into the DI pin on the rising edge of the clock (CLK). The DO pin is normally held in a high-Z state except when reading data from the device, or when checking the READY/BUSY status during a programming operation. The READY/BUSY status can be verified during an Erase/Write operation by polling the DO pin; DO low indicates that programming is still in progress, while DO high indicates the device is ready. The DO will enter the high impedance state on the falling edge of the CS.

#### 3.1 START Condition

The START bit is detected by the device if CS and DI are both HIGH with respect to the positive edge of CLK for the first time.

Before a START condition is detected, CS, CLK, and DI may change in any combination (except to that of a START condition), without resulting in any device operation (READ, WRITE, ERASE, EWEN, EWDS, ERAL, and WRAL). As soon as CS is HIGH, the device is no longer in the standby mode.

An instruction following a START condition will only be executed if the required amount of opcode, address and data bits for any particular instruction are clocked in.

After execution of an instruction (i.e., clock in or out of the last required address or data bit) CLK and DI become don't care bits until a new start condition is detected.

#### 3.2 DI/DO

It is possible to connect the Data In and Data Out pins together. However, with this configuration it is possible for a "bus conflict" to occur during the "dummy zero" that precedes the READ operation, if A0 is a logic HIGH level. Under such a condition the voltage level seen at Data Out is undefined and will depend upon the relative impedances of Data Out and the signal source driving A0. The higher the current sourcing capability of A0, the higher the voltage at the Data Out pin.

#### 3.3 ERASE/WRITE ENABLE AND DISABLE

The 93AA76/86 powers up in the Erase/Write Disable (EWDS) state. All programming modes must be preceded by an Erase/Write Enable (EWEN) instruction. Once the EWEN instruction is executed, programming remains enabled until an EWDS instruction is executed or Vcc is removed from the device. To protect against accidental data disturb, the EWDS instruction can be used to disable all Erase/Write functions and should follow all programming operations. Execution of a READ instruction is independent of both the EWEN and EWDS instructions.

#### 3.4 Data Protection

During power-up, all programming modes of operation are inhibited until Vcc has reached a level greater than 1.4V. During power-down, the source data protection circuitry acts to inhibit all programming modes when Vcc has fallen below 1.4V.

The EWEN and EWDS commands give additional protection against accidentally programming during normal operation.

After power-up, the device is automatically in the EWDS mode. Therefore, an EWEN instruction must be performed before any ERASE or WRITE instruction can be executed.

## 4.0 DEVICE OPERATION

### 4.1 READ

The READ instruction outputs the serial data of the addressed memory location on the DO pin. A dummy zero bit precedes the 16 bit (x16 organization) or 8 bit (x8 organization) output string. The output data bits will toggle on the rising edge of the CLK and are stable after the specified time delay ( $T_{PD}$ ). Sequential read is possible when CS is held high and clock transitions continue. The memory address pointer will automatically increment and output data sequentially.

### 4.2 ERASE

The ERASE instruction forces all data bits of the specified address to the logical "1" state. The self-timed programming cycle is initiated on the rising edge of CLK as the last address bit (A0) is clocked in. At this point, the CLK, CS, and DI inputs become don't cares.

The DO pin indicates the  $\overline{\text{READY}}/\overline{\text{BUSY}}$  status of the device if the CS is high. The  $\overline{\text{READY}}/\overline{\text{BUSY}}$  status will be displayed on the DO pin until the next start bit is received as long as CS is high. Bringing the CS low will place the device in standby mode and cause the DO pin to enter the high impedance state. DO at logical "0" indicates that programming is still in progress. DO at logical "1" indicates that the register at the specified address has been erased and the device is ready for another instruction.

The ERASE cycle takes 3 ms per word (Typical).

### 4.3 WRITE

The WRITE instruction is followed by 16 bits (or by 8 bits) of data to be written into the specified address. The self-timed programming cycle is initiated on the rising edge of CLK as the last data bit (D0) is clocked in. At this point, the CLK, CS, and DI inputs become don't cares.

The DO pin indicates the  $\overline{\text{READY}}/\overline{\text{BUSY}}$  status of the device if the CS is high. The  $\overline{\text{READY}}/\overline{\text{BUSY}}$  status will be displayed on the DO pin until the next start bit is received as long as CS is high. Bringing the CS low will place the device in standby mode and cause the DO pin to enter the high impedance state. DO at logical "0" indicates that programming is still in progress. DO at

logical "1" indicates that the register at the specified address has been written and the device is ready for another instruction.

The WRITE cycle takes 3 ms per word (Typical).

### 4.4 ERASE ALL

The ERAL instruction will erase the entire memory array to the logical "1" state. The ERAL cycle is identical to the ERASE cycle except for the different opcode. The ERAL cycle is completely self-timed and commences on the rising edge of the last address bit (A0). Note that the least significant 8 or 9 address bits are don't care bits, depending on selection of x16 or x8 mode. Clocking of the CLK pin is not necessary after the device has entered the self clocking mode. The ERAL instruction is guaranteed at  $V_{CC} = +4.5V$  to  $+6.0V$ .

The DO pin indicates the  $\overline{\text{READY}}/\overline{\text{BUSY}}$  status of the device if the CS is high. The  $\overline{\text{READY}}/\overline{\text{BUSY}}$  status will be displayed on the DO pin until the next start bit is received as long as CS is high. Bringing the CS low will place the device in standby mode and cause the DO pin to enter the high impedance state. DO at logical "0" indicates that programming is still in progress. DO at logical "1" indicates that the entire device has been erased and is ready for another instruction.

The ERAL cycle takes 15 ms maximum (8 ms typical).

### 4.5 WRITE ALL

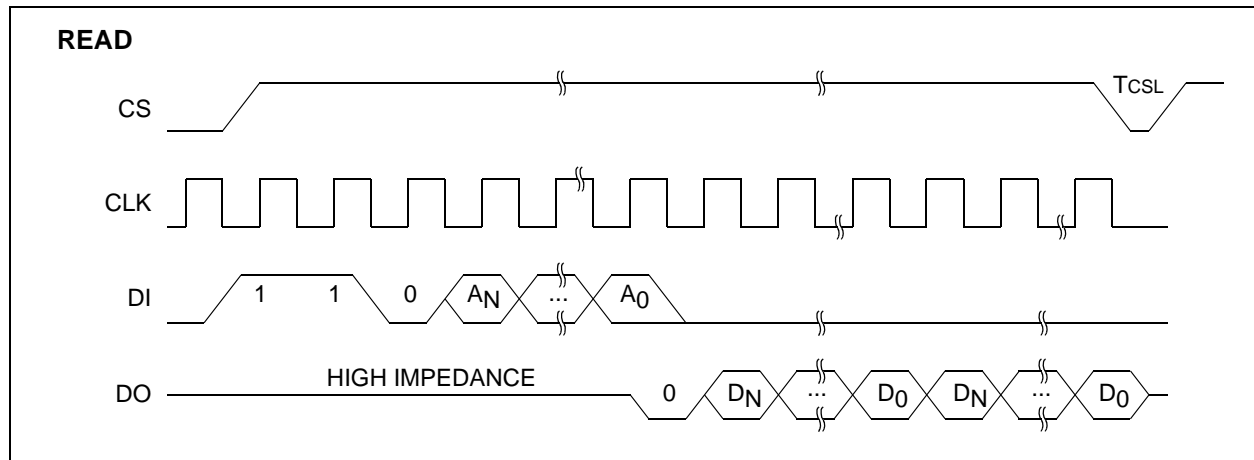

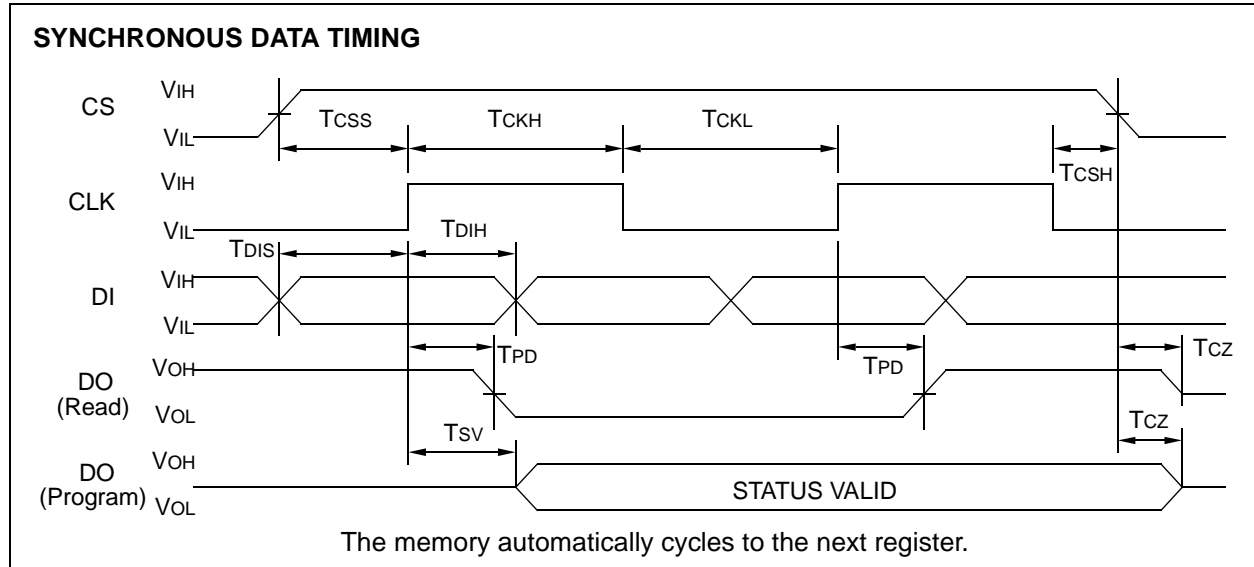

The WRAL instruction will write the entire memory array with the data specified in the command. The WRAL cycle is completely self-timed and commences on the rising edge of the last address bit (A0). Note that the least significant 8 or 9 address bits are don't cares, depending on selection of x16 or x8 mode. Clocking of the CLK pin is not necessary after the device has entered the self clocking mode. The WRAL command does include an automatic ERAL cycle for the device. Therefore, the WRAL instruction does not require an ERAL instruction but the chip must be in the EWEN status. The WRAL instruction is guaranteed at  $V_{CC} = +4.5V$  to  $+6.0V$ .

The DO pin indicates the  $\overline{\text{READY}}/\overline{\text{BUSY}}$  status of the device if the CS is high. The  $\overline{\text{READY}}/\overline{\text{BUSY}}$  status will be displayed on the DO pin until the next start bit is received as long as CS is high. Bringing the CS low will place the device in standby mode and cause the DO pin to enter the high impedance state. DO at logical "0" indicates that programming is still in progress. DO at logical "1" indicates that the entire device has been written and is ready for another instruction.

The WRAL cycle takes 30 ms maximum (16 ms typical).

## Sales and Support

Products supported by a preliminary Data Sheet may possibly have an errata sheet describing minor operational differences and recommended workarounds. To determine if an errata sheet exists for a particular device, please contact one of the following:

1. Your local Microchip sales office (see below).
2. The Microchip Corporate Literature Center U.S. FAX: (602) 786-7277
3. Microchip's Bulletin Board, via your local CompuServe® number (CompuServe membership NOT required).

Please specify which device, revision of silicon and Data Sheet (include Literature #) you are using.

For latest version information and upgrade kits for Microchip Development Tools, please call 1-800-755-2345 or 1-602-786-7302.
