ANALOG DEVICES

Complete 10-Bit, 32 MSPS, 90 mW CMOS A/D Converter

AD9202

FEATURES
CMOS 10-Bit, 32 MSPS Sampling A/D Converter
Power Dissipation: 90 mW (3 V Supply)
Operation Between 2.7 V and 5.5 V Supply
Differential Nonlinearity: 0.5 LSB
Power-Down (Sleep) Mode
Three-State Outputs
Out-of-Range Indicator
Built-In Clamp Function (DC Restore)
Adjustable On-Chip Voltage Reference
IF Undersampling to 135 MHz
Pin-Compatible with the AD9200

PRODUCT DESCRIPTION
The AD9202 is a monolithic, single supply, 10-bit, 32 MSPS analog-to-digital converter with an on-chip sample-and-hold amplifier and voltage reference. The AD9202 uses a multistage differential pipeline architecture at 32 MSPS data rates and guarantees no missing codes over the full operating temperature range.

The input of the AD9202 has been designed to ease the development of both imaging and communications systems. The user can select a variety of input ranges and offsets and can drive the input either single-ended or differentially.

The sample-and-hold (SHA) amplifier is equally suited for both multiplexed systems that switch full-scale voltage levels in successive channels and sampling single-channel inputs at frequencies up to and beyond the Nyquist rate. AC coupled input signals can be shifted to a predetermined level, with an onboard clamp circuit. The dynamic performance is excellent.

The AD9202 has an onboard programmable reference. An external reference can also be chosen to suit the dc accuracy and temperature drift requirements of the application.

A single clock input is used to control all internal conversion cycles. The digital output data is presented in straight binary output format. An out-of-range signal (OTR) indicates an overflow condition that can be used with the most significant bit to determine low or high overflow.

The AD9202 can operate with supply range from 2.7 V to 5.5 V, ideally suiting it for low power operation in high speed portable applications.

The AD9202 is specified over the commercial (0°C to +70°C) temperature range.

PRODUCT HIGHLIGHTS
Low Power
The AD9202 consumes 90 mW on a 3 V supply (excluding the reference power). In sleep mode, power is reduced to below 5 mW.

Very Small Package
The AD9202 is available in a 28-lead SSOP package.

300 MHz Onboard Sample-and-Hold
The versatile SHA input can be configured for either single-ended or differential inputs.

Out-of-Range Indicator
The OTR output bit indicates when the input signal is beyond the input range of the AD9202.

Built-In Clamp Function
Allows dc restoration of video signals.

Pin Compatible with AD9200
The AD9202 allows "drop-in" upgrade for AD9200 users.

CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although the AD9202 features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

DEFINITIONS OF SPECIFICATIONS

Integral Nonlinearity (INL)

Integral nonlinearity refers to the deviation of each individual code from a line drawn from "zero" through "full scale." The point used as "zero" occurs 1/2 LSB before the first code transition. "Full scale" is defined as a level 1 1/2 LSB beyond the last code transition. The deviation is measured from the center of each particular code to the true straight line.

Differential Nonlinearity (DNL, No Missing Codes)

An ideal ADC exhibits code transitions that are exactly 1 LSB apart. DNL is the deviation from this ideal value. It is often specified in terms of the resolution for which no missing codes (NMC) are guaranteed.

Offset Error

The first transition should occur at a level 1/2 LSB above "zero." Offset is defined as the deviation of the actual first code transition from that point.

Gain Error

The first code transition should occur for an analog value 1/2 LSB above nominal negative full scale. The last transition should occur for an analog value 1 1/2 LSB below the nominal positive full scale. Gain error is the deviation of the actual difference between first and last code transitions and the ideal difference between the first and last code transitions.

Pipeline Delay (Latency)

The number of clock cycles between conversion initiation and the associated output data being made available. New output data is provided every rising edge.

APPLYING THE AD9202
THEORY OF OPERATION
The AD9202 implements a pipelined multistage architecture to achieve high sample rate with low power. The AD9202 distributes the conversion over several smaller A/D subblocks, refining the conversion with progressively higher accuracy as it passes the results from stage to stage. As a consequence of the distributed conversion, the AD9202 requires a small fraction of the 1023 comparators used in a traditional flash type A/D. A sample-and-hold function within each of the stages permits the first stage to operate on a new input sample while the second, third and fourth stages operate on the three preceding samples.

OPERATIONAL MODES
The AD9202 is designed to allow optimal performance in a wide variety of imaging, communications and instrumentation applications, including pin compatibility with the AD9200. To realize this flexibility, internal switches on the AD9202 are used to reconfigure the circuit into different modes. These modes are selected by appropriate pin strapping. There are three parts of the circuit affected by this modality: the voltage reference, the reference buffer, and the analog input. The nature of the application will determine which mode is appropriate: the descriptions in the following sections, as well as in Table I, should assist in choosing the desired mode.

Table I. Mode Selection

SUMMARY OF MODES

VOLTAGE REFERENCE

1 V Mode The internal reference may be set to 1 V by connecting REFSENSE and VREF together.

2 V Mode The internal reference my be set to 2 V by connecting REFSENSE to analog ground

External Divider Mode The internal reference may be set to a point between 1 V and 2 V by adding external resistors. See Figure 16f.

External Reference Mode enables the user to apply an external reference to REFTS, REFBS and VREF pins. This mode is attained by tying REFSENSE to VDD.

REFERENCE BUFFER

Center Span Mode midscale is set by shorting REFTS and REFBS together and applying the midscale voltage to that point The MODE pin is set to AVDD/2. The analog input will swing about that midscale point.

Top/Bottom Mode sets the input range between two points. The two points are between 1 V and 2 V apart. The Top/Bottom Mode is enabled by tying the MODE pin to AVDD.

ANALOG INPUT

Differential Mode is attained by driving the AIN pin as one differential input and shorting REFTS and REFBS together and driving them as the second differential input. The MODE pin is tied to AVDD/2. Preferred mode for optimal distortion performance.

Single-Ended is attained by driving the AIN pin while the REFTS and REFBS pins are held at dc points. The MODE pin is tied to AVDD.

Single-Ended/Clamped (AC Coupled) The input may be clamped to some dc level by ac coupling the input. This is done by tying the CLAMPIN to some dc point and applying a pulse to the CLAMP pin. MODE pin is tied to AVDD.

SPECIAL

Users of the AD9200 may upgrade their system by dropping the AD9202 right into their socket.

INPUT AND REFERENCE OVERVIEW

Figure 15, a simplified model of the AD9202, highlights the relationship between the analog input, AIN, and the reference voltages, REFTS, REFBS and VREF. Like the voltages applied to the resistor ladder in a flash A/D converter, REFTS and REFBS define the maximum and minimum input voltages to the A/D.

The input stage is normally configured for single-ended operation, but allows for differential operation by shorting REFTS and REFBS together to be used as the second input.

Figure 15. Equivalent Functional Input Circuit

In single-ended operation, the input spans the range,

$$REFBS \leq AIN \leq REFTS$$

where *REFBS* can be connected to GND and REFTS connected to VREF. If the user requires a different reference range, REFBS and REFTS can be driven to any voltage within the power supply rails, so long as the difference between the two is between 1 V and 2 V.

In differential operation, REFTS and REFBS are shorted together, and the input span is set by VREF,

$$(REFTS - VREF/2) \leq AIN \leq (REFTS + VREF/2)$$

where *VREF* is determined by the internal reference or brought in externally by the user.

The best noise performance may be obtained by operating the AD9202 with a 2 V input range. The best distortion performance may be obtained by operating the AD9202 with a 1 V input range.

REFERENCE OPERATION

The AD9202 can be configured in a variety of reference topologies. The simplest configuration is to use the AD9202's onboard bandgap reference, which provides a pin-strappable option to generate either a 1 V or 2 V output. If the user desires a reference voltage other than those two, an external resistor divider can be connected between VREF, REFSENSE and analog ground to generate a potential anywhere between 1 V and 2 V. Another alternative is to use an external reference for designs requiring enhanced accuracy and/or drift performance. A third alternative is to bring in top and bottom references, bypassing VREF altogether.

Figures 16d, 16e, 16f and 16g illustrate the reference architecture of the AD9202. In tailoring a desired arrangement, the user can select an input configuration to match drive circuit. Then, moving to the reference modes at the bottom of the figure, select a reference circuit to accommodate the offset and amplitude of a full-scale signal.

Table I outlines pin configurations to match user requirements.

REV. A

The actual reference voltages used by the internal circuitry of the AD9202 appear on REFTF and REFBF. For proper operation, it is necessary to add a capacitor network to decouple these pins. The REFTF and REFBF should be decoupled for all internal and external configurations as shown in Figure 17.
Figure 17. Reference Decoupling Network

Note: REFTF = reference top, force
      REFBF = reference bottom, force
      REFTS = reference top, sense
      REFBS = reference bottom, sense

INTERNAL REFERENCE OPERATION
Figures 18, 19 and 20 show example hookups of the AD9202 internal reference in its most common configurations. (Figures 18 and 19 illustrate top/bottom mode while Figure 20 illustrates center span mode). Figure 29 shows how to connect the AD9202 for 1 V p-p differential operation. Shorting the VREF pin directly to the REFSENSE pin places the internal reference amplifier, A1, in unity-gain mode and the resultant reference output is 1 V. In Figure 18 REFBS is grounded to give an input range from 0 V to 1 V. These modes can be chosen when the supply is either +3 V or +5 V. The VREF pin must be bypassed to AVSS (analog ground) with a 1.0 µF tantalum capacitor in parallel with a low inductance, low ESR, 0.1 µF ceramic capacitor.
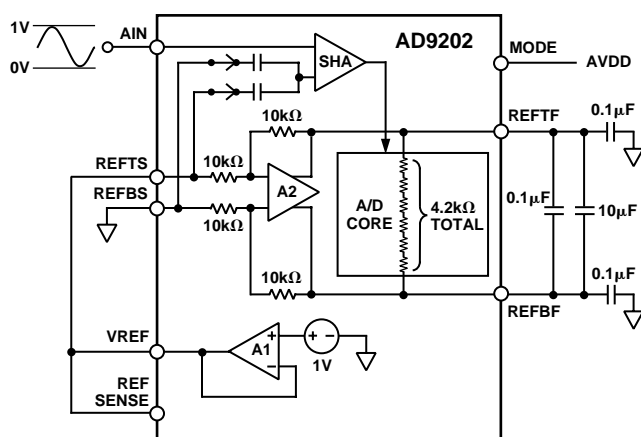

Figure 18. Internal Reference—1 V p-p Input Span (Top/Bottom Mode)

Figure 19 shows the single-ended configuration for 2 V p-p operation. REFSENSE is connected to GND, resulting in a 2 V reference output.
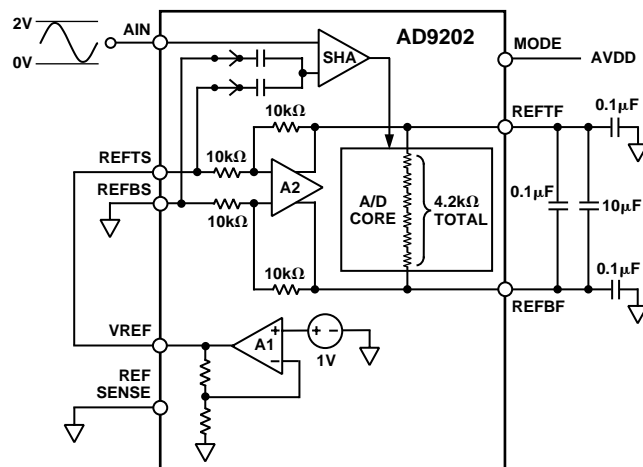

Figure 19. Internal Reference, 2 V p-p Input Span (Top/Bottom Mode)

Figure 20 shows the single-ended configuration that gives the good high frequency dynamic performance (SINAD, SFDR). To optimize dynamic performance, center the common-mode voltage of the analog input at approximately 1.5 V. Connect the shorted REFTS and REFBS inputs to a low impedance 1.5 V source. In this configuration, the MODE pin is driven to a voltage at midsupply (AVDD/2).

Maximum reference drive is 1 mA. An external buffer is required for heavier loads.

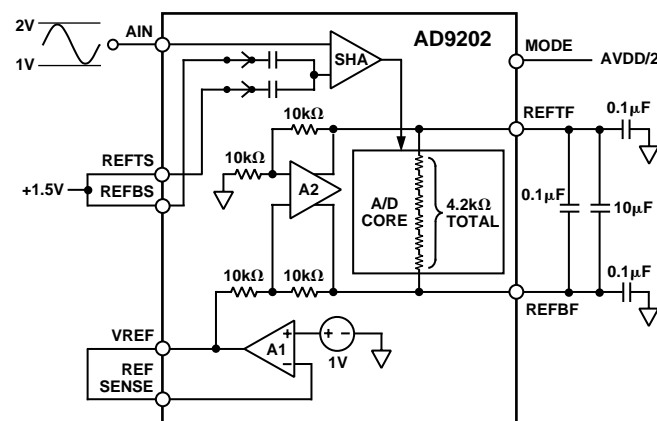

Figure 20. Internal Reference 1 V p-p Input Span (Center Span Mode)

EXTERNAL REFERENCE OPERATION
Using an external reference may provide more flexibility and improve drift and accuracy. Figures 21 through 23 show examples of how to use an external reference with the AD9202. To use an external reference, the user must disable the internal reference amplifier by connecting the REFSENSE pin to VDD. The user then has the option of driving the VREF pin, or driving the REFTS and REFBS pins.

AD9202

The AD9202 contains an internal reference buffer (A2), that simplifies the drive requirements of an external reference. The external reference must simply be able to drive a 10 kΩ load.

Figure 21 shows an example of the user driving the top and bottom references. REFTS is connected to a low impedance 2 V source and REFBS is connected to a low impedance 1 V source. REFTS and REFBS may be driven to any voltage within the supply as long as the difference between them is between 1 V and 2 V.
Figure 21. External Reference Mode—1 V p-p Input Span

Figure 22 shows an example of an external reference generating 2.5 V at the shorted REFTS and REFBS inputs. In this instance, a REF43 2.5 V reference drives REFTS and REFBS. A resistive divider generates a 1 V VREF signal that is buffered by A3. A3 must be able to drive a 10 kΩ, capacitive load. Choose this op amp based on noise and accuracy requirements.
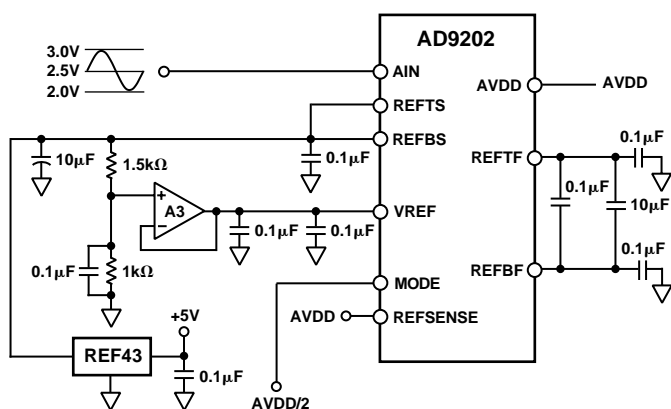

Figure 22. External Reference Mode—1 V p-p Input Span 2.5 V_{CM}

Figure 23a shows an example of the external references driving the REFTF and REFBF pins. REFTS is shorted to REFTF and driven by an external 4 V low impedance source. REFBS is shorted to REFBF and driven by a 2 V source. The MODE pin is connected to GND in this configuration.
Figure 23a. External Reference ~ 2 V p-p Input Span

Figure 23b. Kelvin Connected Reference Using the AD9202

CLAMP OPERATION

The AD9202 feature a clamp circuit for dc restoration of video or ac coupled signals. Figure 24 shows the internal clamp circuitry and the external control signals needed for clamp operation. To enable the clamp, apply a logic high to the CLAMP pin. This will close the switch SW1. The clamp amplifier will then servo the voltage at the AIN pin to be equal to the clamp voltage applied at the CLAMPIN pin. After the desired clamp level is attained, SW1 is opened by taking CLAMP back to a logic low. Ignoring the droop caused by the input bias current, the input capacitor CIN will hold the dc voltage at AIN constant until the next clamp interval. The input resistor RIN has a minimum recommended value of 10 Ω, to maintain the closed-loop stability of the clamp amplifier.

The allowable voltage range that can be applied to CLAMPIN depends on the operational limits of the internal clamp amplifier. When operating off of 3 volt supplies, the recommended clamp range is between 0.5 volts and 2.0 volts.

STANDBY OPERATION

The ADC may be placed into a powered down (sleep) mode by driving the STBY (standby) pin to logic high potential and holding the clock at logic low. In this mode the typical power drain is approximately 3.5 mW. If there is no connection to the STBY pin, an internal pull-down circuit will keep the ADC in a "wake-up" mode of operation.

The ADC will "wake up" in 400 ns (typ) after the standby pulse goes low.

The input capacitor should be sized to allow sufficient acquisition time of the clamp voltage at AIN within the CLAMP interval, but also be sized to minimize droop between clamping intervals. Specifically, the acquisition time when the switch is closed will equal:

$$T_{ACQ} = R_{IN}C_{IN}\ ln\left(\frac{V_C}{V_E}\right)$$

where V_C is the voltage change required across C_{IN}, and V_E is the error voltage. V_C is calculated by taking the difference between the initial input dc level at the start of the clamp interval and the clamp voltage supplied at CLAMPIN. V_E is a system dependent parameter, and equals the maximum tolerable deviation from V_C. For example, if a 2-volt input level needs to be clamped to 1 volt at the AD9202's input within 10 millivolts, then V_C equals 2 – 1 or 1 volt, and V_E equals 10 mV. Note that once the proper clamp level is attained at the input, only a very small voltage change will be required to correct for droop.

The voltage droop is calculated with the following equation:

$$dV = \frac{I_{BIAS}}{C_{IN}}(t)$$

where t = time between clamping intervals.

The bias current of the AD9202 will depend on the sampling rate, F_S. The switched capacitor input AIN appears resistive over time, with an input resistance equal to $1/C_SF_S$. Given a sampling rate of 32 MSPS and an input capacitance of 1 pF, the input resistance is 31.2 kΩ. This input resistance is equivalently terminated at the midscale voltage of the input range. The worst case bias current will thus result when the input signal is at the extremes of the input range, that is, the furthest distance from the midscale voltage level. For a 1-volt input range, the maximum bias current will be ±0.5 volts divided by 50 kΩ, which is ±10 µA.

If droop is a critical parameter, the minimum value of C_{IN} should be calculated first based on the droop requirement. Acquisition time—the width of the CLAMP pulse—can be adjusted accordingly once the minimum capacitor value is chosen. A tradeoff will often need to be made between droop and acquisition time, or error voltage V_E.

Clamp Circuit Example
A single supply video amplifier outputs a level-shifted video signal between 2 and 3 volts with the following parameters:

horizontal period = 63.56 µs,
horizontal sync interval = 10.9 µs,
horizontal sync pulse = 4.7 µs,
sync amplitude = 0.3 volts,
video amplitude of 0.7 volts,
reference black level = 2.3 volts

The video signal must be dc restored from a 2- to 3-volt range down to a 1- to 2-volt range. Configuring the AD9202 for a one volt input span with an input range from 1 to 2 volts (see Figure 24), the CLAMPIN voltage can be set to 1 volt with an external voltage or by direct connection to REFBS. The CLAMP

pulse may be applied during the SYNC pulse, or during the back porch to truncate the SYNC below the AD9202's minimum input voltage. With a C_{IN} = 1 µF, and R_{IN} = 20 Ω, the acquisition time needed to set the input dc level to 1 volt with 1 mV accuracy is about 140 µs, assuming a full 1 volt V_C.

With a 1 µF input coupling capacitor, the droop across one horizontal can be calculated:

I_{BIAS} = 10 µA, and t = 63.5 µs, so dV = 0.635 mV, which is less than one LSB.

After the input capacitor is initially charged, the clamp pulse width only needs to be wide enough to correct small voltage errors such as the droop. The fine scale settling characteristics of the clamp circuitry are shown in Table II.

Depending on the required accuracy, a CLAMP pulse width of 1 µs–3 µs should work in most applications. The OFFSET values ignore the contribution of offset from the clamp amplifier; they simply compare the output code with a "final value" measured with a much longer CLAMP pulse duration.

Table II.

| CLAMP	OFFSET
10 µs	<1 LSB
5 µs	5 LSBs
4 µs	7 LSBs
3 µs	11 LSBs
2 µs	19 LSBs
1 µs	42 LSBs

AD9202

DRIVING THE ANALOG INPUT
Figure 25 shows the equivalent analog input of the AD9202, a sample-and-hold amplifier (switched capacitor input SHA). Bringing CLK to a logic low level closes Switches 1 and 2 and opens Switch 3. The input source connected to AIN must charge capacitor CH during this time. When CLK transitions from logic "low" to logic "high," Switches 1 and 2 open, placing the SHA in hold mode. Switch 3 then closes, forcing the output of the op amp to equal the voltage stored on CH. When CLK transitions from logic "high" to logic "low," Switch 3 opens first. Switches 1 and 2 close, placing the SHA in track mode.
Figure 25. Equivalent Input Structure

The structure of the input SHA places certain requirements on the input drive source. The combination of the pin capacitance, CP, and the hold capacitance, CH, is typically less than 5 pF. The input source must be able to charge or discharge this capacitance to 10-bit accuracy in one half of a clock cycle. When the SHA goes into track mode, the input source must charge or discharge capacitor CH from the voltage already stored on CH to the new voltage. In the worst case, a full-scale voltage step on the input, the input source must provide the charging current through the R_{ON} (50 Ω) of Switch 1 and quickly (within 1/2 CLK period) settle. This situation corresponds to driving a low input impedance. On the other hand, when the source voltage equals the value previously stored on CH, the hold capacitor requires no input current and the equivalent input impedance is extremely high.

Adding series resistance between the output of the source and the AIN pin reduces the drive requirements placed on the source. Figure 26 shows this configuration. The bandwidth of the particular application limits the size of this resistor. To maintain the performance outlined in the data sheet specifications, the resistor should be limited to 20 Ω or less. For applications with signal bandwidths less than 10 MHz, the user may proportionally increase the size of the series resistor. Alternatively, adding a shunt capacitance between the AIN pin and analog ground can lower the ac load impedance. The value of this capacitance will depend on the source resistance and the required signal bandwidth.

The input span of the AD9202 is a function of the reference voltages. For more information regarding the input range, see the Internal and External Reference sections of the data sheet.

Figure 26. Simple Drive Configuration

In many cases, particularly in single-supply operation, ac coupling offers a convenient way of biasing the analog input signal at the proper signal range. Figure 27 shows a typical configuration for ac-coupling the analog input signal to the AD9202. Maintaining the specifications outlined in the data sheet requires careful selection of the component values. The most important is the $f_{-3\ dB}$ high-pass corner frequency. It is a function of R2 and the parallel combination of C1 and C2. The $f_{-3\ dB}$ point can be approximated by the equation:

$$f_{-3\ dB} = 1/(2 \times pi \times [R2]\ C_{EQ})$$

where C_{EQ} is the parallel combination of C1 and C2. Note that C1 is typically a large electrolytic or tantalum capacitor that becomes inductive at high frequencies. Adding a small ceramic or polystyrene capacitor (on the order of 0.01 μF) that does not become inductive until negligibly higher frequencies, maintains a low impedance over a wide frequency range.

NOTE: AC-coupled input signals may also be shifted to a desired level with the AD9202's internal clamp. See Clamp Operation.

Figure 27. AC-Coupled Input

There are additional considerations when choosing the resistor values. The ac-coupling capacitors integrate the switching transients present at the input of the AD9202 and cause a net dc bias current, I_B, to flow into the input. The magnitude of the bias current increases as the signal magnitude deviates from V midscale and the clock frequency increases; i.e., minimum bias current flow when AIN = V midscale. This bias current will result in an offset error of $(R1 + R2) \times I_B$. If it is necessary to compensate this error, consider making R2 negligibly small or modifying VBIAS to account for the resultant offset.

In systems that must use dc coupling, use an op amp to level-shift a ground-referenced signal to comply with the input requirements of the AD9202. Figure 28 shows an AD8041 configured in noninverting mode.

Figure 28. Bipolar Level Shift

DIFFERENTIAL INPUT OPERATION

The AD9202 will accept differential input signals. This function may be used by shorting REFTS and REFBS and driving them as one leg of the differential signal (the top leg is driven into AIN). In the configuration below, the AD9202 is accepting a 1 V p-p signal. See Figure 29.

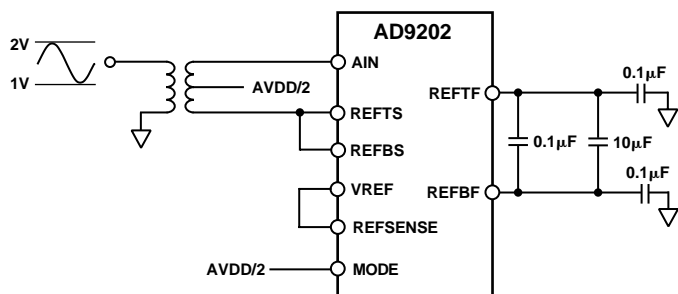

Figure 29. Differential Input

CLOCK INPUT

The AD9202 clock input is buffered internally with an inverter powered from the AVDD pin. This feature allows the AD9202 to accommodate either +5 V or +3.3 V CMOS logic input signal swings with the input threshold for the CLK pin nominally at AVDD/2.

The pipelined architecture of the AD9202 operates on both rising and falling edges of the input clock. To minimize duty cycle variations the recommended logic family to drive the clock input is high speed or advanced CMOS (HC/HCT, AC/ACT) logic. CMOS logic provides both symmetrical voltage threshold levels and sufficient rise and fall times to support 32 MSPS operation. The AD9202 is designed to support a conversion rate of MSPS; running the part at slightly faster clock rates may be possible, although at reduced performance levels. Conversely, some slight performance improvements might be realized by clocking the AD9202 at slower clock rates.

Figure 30. Timing Diagram

The power dissipated by the output buffers is largely proportional to the clock frequency; running at reduced clock rates provides a reduction in power consumption.

DIGITAL INPUTS AND OUTPUTS

Each of the AD9202 digital control inputs, THREE-STATE and STBY are reference to analog ground. The clock is also referenced to analog ground.

The format of the digital output is straight binary (see Figure 31). A low power mode feature is provided such that for STBY = HIGH and the clock disabled, the static power of the AD9202 will drop below 5 mW.

APPLICATIONS

DIRECT IF DOWN CONVERSION USING THE AD9202

Sampling IF signals above an ADC's baseband region (i.e., dc to $F_S/2$) is becoming increasingly popular in communication applications. This process is often referred to as Direct IF Down Conversion or Undersampling. There are several potential benefits in using the ADC to alias (i.e., or mix) down a narrowband or wideband IF signal. First and foremost is the elimination of a complete mixer stage with its associated amplifiers and filters, reducing cost and power dissipation. Second is the ability to apply various DSP techniques to perform such functions as filtering, channel selection, quadrature demodulation, data reduction, detection, etc. A detailed discussion on using this technique in digital receivers can be found in Analog Devices Application Notes AN-301 and AN-302.

In Direct IF Down Conversion applications, one exploits the inherent sampling process of an ADC in which an IF signal lying outside the baseband region can be aliased back into the baseband region in a similar manner that a mixer will down-convert an IF signal. Similar to the mixer topology, an image rejection filter is required to limit other potential interfering signals from also aliasing back into the ADC's baseband region. A tradeoff exists between the complexity of this image rejection filter and the sample rate as well as dynamic range of the ADC.

The AD9202 is well suited for various narrowband IF sampling applications. The AD9202's low distortion input SHA has a full-power bandwidth extending to 300 MHz thus encompassing many popular IF frequencies. A DNL of ±0.5 LSB (typ) combined with low thermal input referred noise allows the AD9202 in the 2 V span to provide 60 dB of SNR for a baseband input sine wave. Also, its low aperture jitter of 2 ps rms ensures minimum SNR degradation at higher IF frequencies. In fact, the AD9202 is capable of still maintaining 50 dB of SNR at an IF of 135 MHz with a 1 V (i.e., 4 dBm) input span. Note, although the AD9202 will typically yield a 3 to 4 dB improvement in SNR when configured for the 2 V span, the 1 V span provides the optimum full-scale distortion performance. Furthermore, the 1 V span reduces the performance requirements of the input driver circuitry and thus may be more practical for system implementation purposes.
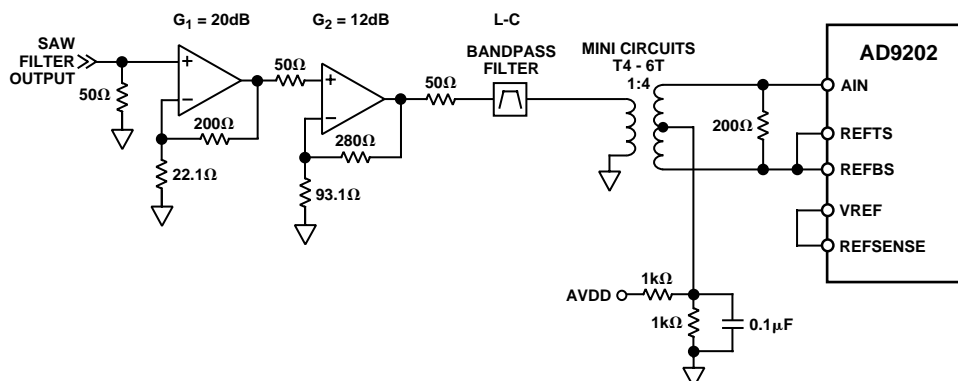

AD9202

Figure 33. Simplified IF Sampling Circuit

Figure 33 shows a simplified schematic of the AD9202 configured in an IF sampling application. To reduce the complexity of the digital demodulator in many quadrature demodulation applications, the IF frequency and/or sample rate are selected such that the bandlimited IF signal aliases back into the center of the ADC's baseband region (i.e., $F_S/4$). For example, if an IF signal centered at 45 MHz is sampled at 20 MSPS, an image of this IF signal will be aliased back to 5.0 MHz which corresponds to one quarter of the sample rate (i.e., $F_S/4$). This demodulation technique typically reduces the complexity of the post digital demodulator ASIC which follows the ADC.

To maximize its distortion performance, the AD9202 is configured in the differential mode with a 1 V span using a transformer. The center tap of the transformer is biased at midsupply via a resistor divider. Preceding the AD9202 is a bandpass filter as well as a 32 dB gain stage. A large gain stage may be required to compensate for the high insertion losses of a SAW filter used for image rejection. The gain stage will also provide adequate isolation for the SAW filter from the charge "kick back" currents associated with AD9202's input stage.

The gain stage can be realized using one or two cascaded AD8009 op amps amplifiers. The AD8009 is a low cost, 1 GHz, current-feedback op amp having a 3rd order intercept characterized up to 250 MHz. A passive bandpass filter following the AD8009 attenuates its dominant 2nd order distortion products which would otherwise be aliased back into the AD9202's baseband region. Also, it reduces any out-of-band noise which would also be aliased back due to the AD9202's noise bandwidth of 220+ MHz. Note, the bandpass filters specifications are application dependent and will affect both the total distortion and noise performance of this circuit.

The distortion and noise performance of an ADC at the given IF frequency is of particular concern when evaluating an ADC for a narrowband IF sampling application. Both single-tone and dual-tone SFDR vs. amplitude are very useful in an assessing an ADC's noise performance and noise contribution due to aperture jitter. In any application, one is advised to test several units of the same device under the same conditions to evaluate the given applications sensitivity to that particular device.

Figures 34–37 combine the dual-tone SFDR as well as single tone SFDR and SNR performance at IF frequencies of 45 MHz, 70 MHz, 85 MHz and 135 MHz. Note, the SFDR vs. amplitude data is referenced to dBFS while the single tone SNR data is referenced to dBc. The performance characteristics in these figures are representative of the AD9202 without the AD8009. The AD9202 was operated in the differential mode (via transformer) with a 1 V span.

Figure 34. SNR/SFDR for IF @ 45 MHz (Clock = 27.5 MHz)

Figure 35. SNR/SFDR for IF @ 70 MHz (Clock = 31.1 MHz)

Figure 36. SNR/SFDR for IF @ 85 MHz (Clock = 30.9 MHz)

Figure 37. SNR/SFDR for IF @ 135 MHz (Clock = 32 MHz)

Although not presented, data was also taken with the insertion of an AD8009 gain stage of 32 dB in the signal path. No degradation in two-tone SFDR vs. amplitude was noted at an IF of 45 MHz, 70 MHz and 85 MHz. However, at 135 MHz, the AD8009 became the limiting factor in the distortion performance until the two input tones were decreased to –15 dBFS from their full-scale level of –6.5 dBFS. Note: the SNR performance in each case degraded by approximately 0.5 dB due to the AD8009's in-band noise contribution.

GROUNDING AND LAYOUT RULES

As is the case for any high performance device, proper grounding and layout techniques are essential in achieving optimal performance. The analog and digital grounds on the AD9202 have been separated to optimize the management of return currents in a system. Grounds should be connected near the ADC. It is recommended that a printed circuit board (PCB) of at least four layers, employing a ground plane and power planes, be used with the AD9202. The use of ground and power planes offers distinct advantages:

1. The minimization of the loop area encompassed by a signal and its return path.

2. The minimization of the impedance associated with ground and power paths.

3. The inherent distributed capacitor formed by the power plane, PCB insulation and ground plane.

These characteristics result in both a reduction of electromagnetic interference (EMI) and an overall improvement in performance.

It is important to design a layout that prevents noise from coupling onto the input signal. Digital signals should not be run in parallel with the input signal traces and should be routed away from the input circuitry. Separate analog and digital grounds should be joined together directly under the AD9202 in a solid ground plane. The power and ground return currents must be carefully managed. A general rule of thumb for mixed signal layouts dictates that the return currents from digital circuitry should not pass through critical analog circuitry.

DIGITAL OUTPUTS

Each of the on-chip buffers for the AD9202 output bits (D0–D9) is powered from the DRVDD supply pins, separate from AVDD. The output drivers are sized to handle a variety of logic families while minimizing the amount of glitch energy generated. In all cases, a fan-out of one is recommended to keep the capacitive load on the output data bits below the specified 20 pF level.

For DRVDD = 5 V, the AD9202 output signal swing is compatible with both high speed CMOS and TTL logic families. For TTL, the AD9202 on-chip, output drivers were designed to support several of the high speed TTL families (F, AS, S). For applications where the clock rate is below MSPS, other TTL families may be appropriate. For interfacing with lower voltage CMOS logic, the AD9202 sustains MSPS operation with DRVDD = 3 V. In all cases, check your logic family data sheets for compatibility with the AD9202 Digital Specification table.

THREE-STATE OUTPUTS

The digital outputs of the AD9202 can be placed in a high impedance state by setting the THREE-STATE pin to HIGH. This feature is provided to facilitate in-circuit testing or evaluation.
