

## Features

- Incorporates the ARM7TDMI™ ARM® Thumb® Processor Core
  - High-performance 32-bit RISC Architecture
  - High-density 16-bit Instruction Set
  - Leader in MIPS/Watt
  - Embedded ICE (In-Circuit Emulation)
- On-chip SRAM and/or ROM
  - 32-bit Data Bus
  - Single-clock Cycle Access
- Fully Programmable External Bus Interface (EBI)
  - Maximum External Address Space of 64M Bytes
  - Up to 8 Chip Selects
  - Software Programmable 8/16-bit External Databus
- 8-level Priority, Individually Maskable, Vectored Interrupt Controller
  - 4 External Interrupts, Including a High-priority Low-latency Interrupt Request
- 32 Programmable I/O Lines
- 3-channel 16-bit Timer/Counter
  - 3 External Clock Inputs
  - 2 Multi-purpose I/O Pins per Channel
- 2 USARTs
  - 2 Dedicated Peripheral Data Controller (PDC) Channels per USART
- Programmable Watchdog Timer
- Advanced Power-saving Features
  - CPU and Peripheral Can be Deactivated Individually
- Fully Static Operation:
  - 0 Hz to 16 MHz at 1.8V
  - 0 Hz to 33 MHz at 2.7V
  - 0 Hz to 40 MHz at 3.0V
- 1.8V to 3.6V Operating Range
- Available in a 100-lead TQFP Package

Microcontroller	SRAM	Extended SRAM	ROM
AT91M40800	8K Byte	–	–
AT91R40807	8K Byte	128K Byte	–
AT91M40807	8K Byte	–	128K Byte

## Description

The AT91X40 Series is a member of the Atmel AT91 16/32-bit Microcontroller family, which is based on the ARM7TDMI processor core. This processor has a high-performance 32-bit RISC architecture with a high-density 16-bit instruction set and very low power consumption. In addition, a large number of internally banked registers result in very fast exception handling, making the device ideal for real-time control applications.

The AT91X40 Series features a direct connection to off-chip memory, including Flash, through the fully programmable External Bus Interface (EBI). An eight-level priority vectored interrupt controller, in conjunction with the Peripheral Data Controller significantly improve the real-time performance of the device.

The device is manufactured using Atmel's high-density CMOS technology. By combining the ARM7TDMI processor core with on-chip high-speed memory and a wide range of peripheral functions on a monolithic chip, the Atmel AT91X40 Series is a powerful microcontroller that offers a flexible, cost-effective solution to many compute-intensive embedded control applications.

## Block Diagram

Figure 2. AT91X40 Series

## Architectural Overview

The AT91X40 Series Microcontroller integrates an ARM7TDMI with its Embedded ICE interface, memories and peripherals. Its architecture consists of two main buses, the Advanced System Bus (ASB) and the Advanced Peripheral Bus (APB). Designed for maximum performance and controlled by the memory controller, the ASB interfaces the ARM7TDMI processor with the on-chip 32-bit memories, the External Bus Interface (EBI) and the AMBA Bridge. The AMBA Bridge drives the APB, which is designed for accesses to on-chip peripherals and optimized for low-power consumption.

The AT91X40 Series Microcontrollers implement the ICE port of the ARM7TDMI processor on dedicated pins, offering a complete, low-cost and easy-to-use debug solution for target debugging.

### Memories

The AT91X40 Series Microcontrollers embed up to 136K bytes of internal SRAM, and up to 128K bytes of ROM. The internal memories are directly connected to the 32-bit data bus and are single-cycle accessible. This provides maximum performance of 36 MIPS at 40 MHz by using the ARM instruction set of the processor, minimizing system power consumption and improving the performance of separate memory solutions.

The AT91X40 Series Microcontrollers feature an External Bus Interface (EBI), which enables connection of external memories and application-specific peripherals. The EBI supports 8- or 16-bit devices and can use two 8-bit devices to emulate a single 16-bit device. The EBI implements the early read protocol, enabling faster memory accesses than standard memory interfaces.

### Peripherals

The AT91X40 Series Microcontrollers integrate several peripherals, which are classified as system or user peripherals. All on-chip peripherals are 32-bit accessible by the AMBA Bridge, and can be programmed with a minimum number of instructions. The peripheral register set is composed of control, mode, data, status and enable/disable/status registers.

An on-chip Peripheral Data Controller (PDC) transfers data between the on-chip USARTs and on- and off-chip memories address space without processor intervention. Most importantly, the PDC removes the processor interrupt handling overhead, making it possible to transfer up to 64K continuous bytes without reprogramming the start address, thus increasing the performance of the microcontroller, and reducing the power consumption.

### System Peripherals

The External Bus Interface (EBI) controls the external memory or devices via an 8-bit or 16-bit database, and is programmed through the APB. Each chip select line has its own programming register.

The Power Saving (PS) module implements the Idle Mode (ARM7TDMI core clock stopped until the next interrupt) and enables the user to adapt the power consumption of the microcontroller to application requirements (independent peripheral clock control).

The Advanced Interrupt Controller (AIC) controls the internal sources from the internal peripherals and the four external interrupt lines (including the FIQ) to provide an interrupt and/or fast interrupt request to the ARM7TDMI. It integrates an 8-level priority controller, and, using the Auto-vectoring feature, reduces the interrupt latency time.

The Parallel Input/Output Controller (PIO) controls up to 32 I/O lines. It enables the user to select specific pins for on-chip peripheral input/output functions, and general-purpose input/output signal pins. The PIO controller can be programmed to detect an interrupt on a signal change from each line.

The Watchdog (WD) can be used to prevent system lock-up if the software becomes trapped in a deadlock.

The Special Function (SF) module integrates the Chip ID, the Reset Status and the Protect registers.

### User Peripherals

Two USARTs, independently configurable, enable communication at a high baud rate in Synchronous or Asynchronous Mode. The format includes start, stop and parity bits and up to 8 data bits. Each USART also features a Timeout and a Time Guard register, facilitating the use of the two dedicated Peripheral Data Controller (PDC) channels.

The 3-channel, 16-bit Timer Counter (TC) is highly-programmable and supports Capture or Waveform Modes. Each TC channel can be programmed to measure or generate different kinds of waves, and can detect and control two input/output signals. The TC has also 3 external clock signals.

## Product Overview

### Power Supply

The AT91X40 Series Microcontrollers have a single type of power supply pin—VDD. The VDD pin supplies the I/O pads and the device core. The supported voltage range on VDD is 1.8V to 3.6V.

### Input/Output Considerations

The AT91M40807 and AT91R40807 accept voltage levels up to their power supply limit on the pads.

The AT91M40800 Microcontroller I/O pads are 5V-tolerant, enabling it to interface with external 5V devices without any additional components. 5V-tolerant means that the AT91M40800 accepts 5V (3V) on the inputs even if it is powered at 3V (2V). Refer to the AT91M40800 Electrical Characteristics datasheet for further detail.

After the reset, the peripheral I/Os are initialized as inputs to provide the user with maximum flexibility. It is recommended that in any application phase, the inputs to the AT91X40 Series Microcontroller be held at valid logic levels to minimize the power consumption.

### Master Clock

The AT91X40 Series Microcontrollers have a fully static design and work on the Master Clock (MCK), provided on the MCKI pin from an external source.

The Master Clock is also provided as an output of the device on the pin MCKO, which is multiplexed with a general-purpose I/O line. While NRST is active, the MCKO stays low. After the reset, the MCKO is valid and outputs an image of the MCK signal. The PIO Controller must be programmed to use this pin as standard I/O line.

### Reset

Reset restores the default states of the user interface registers (defined in the user interface of each peripheral), and forces the ARM7TDMI to perform the next instruction fetch from address zero. Except for the program counter the ARM7TDMI registers do not have defined reset states.

### NRST Pin

NRST is active low-level input. It is asserted asynchronously, but exit from reset is synchronized internally to the MCK. The signal presented on MCK must be active within the specification for a minimum of 10 clock cycles up to the rising edge of NRST, to ensure correct operation. The first processor fetch occurs 80 clock cycles after the rising edge of NRST.

### Watchdog Reset

The watchdog can be programmed to generate an internal reset. In this case, the reset has the same effect as the NRST pin assertion, but the pins BMS and NTRI are not sampled. Boot Mode and Tri-state Mode are not updated. If the NRST pin is asserted and the watchdog triggers the internal reset, the NRST pin has priority.

### Emulation Function

#### Tri-state Mode

The AT91X40 Series provides a Tri-state Mode, which is used for debug purposes. This enables the connection of an emulator probe to an application board without having to desolder the device from the target board. In Tri-state Mode, all the output pin drivers of the AT91X40 Series Microcontroller are disabled.

To enter Tri-state Mode, the pin NTRI must be held low during the last 80 clock cycles before the rising edge of NRST. For normal operation, the pin NTRI must be held high during reset, by a resistor of up to 400K Ohm.

NTRI is multiplexed with I/O line P21 and USART 1 serial data transmit line TXD1.

Standard RS232 drivers generally contain internal 400K Ohm pull-up resistors. If TXD1 is connected to a device not including this pull-up, the user must make sure that a high level is tied on NTRI while NRST is asserted.

#### JTAG/ICE Debug

ARM standard embedded In-circuit Emulation is supported via the JTAG/ICE port. The pins TDI, TDO, TCK and TMS are dedicated to this debug function and can be connected to a host computer via the external ICE interface.

In ICE Debug Mode, the ARM7TDMI core responds with a non-JTAG chip ID that identifies the microcontroller. This is not fully IEEE1149.1 compliant.

### Memory Controller

The ARM7TDMI processor address space is 4G bytes. The memory controller decodes the internal 32-bit address bus and defines three address spaces:

- Internal Memories in the four lowest megabytes
- Middle Space reserved for the external devices (memory or peripherals) controlled by the EBI
- Internal Peripherals in the four highest megabytes

In any of these address spaces, the ARM7TDMI operates in Little-Endian Mode only.

## Internal Memories

The AT91X40 Series Microcontrollers integrate internal static SRAM and/or ROM. All internal memories are 32 bits wide and single-clock cycle accessible.

The AT91X40 Series Microcontrollers integrate a primary 1-Kbyte or 8-Kbyte SRAM bank. This memory bank is mapped at address 0x0 (after the remap command), allowing ARM7TDMI exception vectors between 0x0 and 0x20 to be modified by the software. The rest of the bank can be used for stack allocation (to speed up context saving and restoring), or as data and program storage for critical algorithms.

The AT91R40807 integrates an extended memory bank of 128K bytes at address 0x0010 0000. Placing the SRAM on-chip and using the 32-bit data bus bandwidth maximizes the microcontroller performance and minimizes the system power consumption. The 32-bit bus increases the effectiveness of the use of the ARM instruction set, and the ability of processing data that is wider than 16-bit, thus making optimal use of the ARM7TDMI advanced performance.

Being able to dynamically update application software in the 128-Kbyte SRAM adds an extra dimension to the AT91R40807. This 128-Kbyte SRAM can also be used to validate the code to be stored in the on-chip ROM memory prior to mass production of the AT91M40807. At system boot, the code is downloaded from external non-volatile memory to this on-chip extended SRAM. In order to prevent accidental write to the extended SRAM during the ROM emulation, a write detection feature has been implemented.

The AT91M40807 Microcontroller ROM version integrates 128K bytes of internal ROM at address 0x0010 0000. The ROM versions offer a reduced-cost option of the AT91R40807 for high-volume applications in which the software is stable.

## Boot Mode Select

The ARM reset vector is at address 0x0. After the NRST line is released, the ARM7TDMI executes the instruction stored at this address. This means that this address must be mapped in non-volatile memory after the reset.

The input level on the BMS pin during the last 10 clock cycles before the rising edge of the NRST selects the type of boot memory. The Boot Mode depends on BMS and whether or not the AT91X40 Series Microcontroller has on-chip ROM or extended SRAM (see Table 3).

The AT91R40807 supports boot in on-chip extended SRAM, for the purpose of emulating ROM versions. In this case, the microcontroller must first boot from external non-volatile memory, and ensure that a valid program is downloaded in the on-chip extended SRAM. Then, the NRST

must be reasserted by external circuitry after the level on the pin BMS is changed.

The pin BMS is multiplexed with the I/O line P24 that can be programmed after reset like any standard PIO line.

**Table 3.** Boot Mode Select

BMS	Product	Boot Memory
1	AT91M40800	External 8-bit memory on NCS0
	AT91R40807	Internal 32-bit extended SRAM
	AT91M40807	Internal 32-bit ROM
0	All	External 16-bit memory on NCS0

## Remap Command

The ARM vectors (Reset, Abort, Data Abort, Prefetch Abort, Undefined Instruction, Interrupt, Fast Interrupt) are mapped from address 0x0 to address 0x20. In order to allow these vectors to be redefined dynamically by the software, the AT91X40 Series Microcontrollers use a remap command that enables switching between the boot memory and the internal primary SRAM bank addresses. The remap command is accessible through the EBI User Interface, by writing one in RCB of EBI\_RCR (Remap Control Register). Performing a remap command is mandatory if access to the other external devices (connected to chip selects 1 to 7) is required. The remap operation can only be changed back by an internal reset or an NRST assertion.

## Abort Control

The abort signal providing a Data Abort or a Prefetch Abort exception to the ARM7TDMI is asserted in the following cases:

- When accessing an undefined address in the EBI address space
- When writing to a write-protected internal memory area on the AT91R40807

No abort is generated when reading the internal memory or by accessing the internal peripheral, whether the address is defined or not.

When a write-protected area is accessed, the memory controller detects it and generates an abort but does not cancel the access.

## External Bus Interface

The External Bus Interface handles the accesses between addresses 0x0040 0000 and 0xFFC0 0000. It generates the signals that control access to the external devices, and can be configured from eight 1M-byte banks up to four 16M-byte banks. It supports byte, half-word and word aligned accesses.

For each of these banks, the user can program:

- Number of wait states
- Number of data float times (wait time after the access is finished to prevent any bus contention in case the device is too long in releasing the bus)
- Data bus width (8-bit or 16-bit)
- With a 16-bit wide data bus, the user can program the EBI to control one 16-bit device (Byte Access Select Mode) or two 8-bit devices in parallel that emulate a 16-bit memory (Byte Write Access Mode).

The External Bus Interface features also the Early Read Protocol, configurable for all the devices, that significantly reduces access time requirements on an external device in the case of single clock cycle access.

## Peripherals

The AT91X40 Series peripherals are connected to the 32-bit wide Advanced Peripheral Bus. Peripheral registers are only word accessible—byte and half-word accesses are not supported. If a byte or a half-word access is attempted, the memory controller automatically masks the lowest address bits and generates a word access.

Each peripheral has a 16-Kbyte address space allocated (the AIC only has a 4-Kbyte address space).

### Peripheral Registers

The following registers are common to all peripherals:

- Control Register—write only register that triggers a command when a one is written to the corresponding position at the appropriate address. Writing a zero has no effect.
- Mode Register—read/write register that defines the configuration of the peripheral. Usually has a value of 0x0 after a reset.
- Data Registers—read and/or write register that enables the exchange of data between the processor and the peripheral.
- Status Register—read only register that returns the status of the peripheral.
- Enable/Disable/Status Registers are shadow command registers. Writing a one in the Enable Register sets the corresponding bit in the Status Register. Writing a one in the Disable Register resets the corresponding bit and the result can be read in the Status Register. Writing a bit to zero has no effect. This register access method maximizes the efficiency of bit manipulation, and enables modification of a register with a single non-interruptible instruction, replacing the costly read-modify-write operation.

Unused bits in the peripheral registers are shown as “–” and must be written at 0 for upward compatibility. These bits read 0.

### Peripheral Interrupt Control

The Interrupt Control of each peripheral is controlled from the status register using the interrupt mask. The status register bits are ANDed to their corresponding interrupt mask bits and the result is then ORed to generate the Interrupt Source signal to the Advanced Interrupt Controller.

The interrupt mask is read in the Interrupt Mask Register and is modified with the Interrupt Enable Register and the Interrupt Disable Register. The enable/disable/status (or mask) makes it possible to enable or disable peripheral interrupt sources with a non-interruptible single instruction. This eliminates the need for interrupt masking at the AIC or Core level in real-time and multi-tasking systems.

### Peripheral Data Controller

The AT91X40 Series Microcontroller has a 4-channel PDC dedicated to the two on-chip USARTs. One PDC channel is dedicated to the receiver and one to the transmitter of each USART.

The user interface of a PDC channel is integrated in the memory space of each USART. It contains a 32-bit Address Pointer Register (RPR or TPR) and a 16-bit Transfer Counter Register (RCR or TCR). When the programmed number of transfers are performed, a status bit indicating the end of transfer is set in the USART Status Register and an interrupt can be generated.

## System Peripherals

### PS: Power-saving

The Power-saving feature optimizes power consumption, enabling the software to stop the ARM7TDMI clock (Idle Mode) and restarting it when the module receives an interrupt (or reset). It also enables on-chip peripheral clocks to be enabled and disabled individually, matching power consumption and application needs.

### AIC: Advanced Interrupt Controller

The AIC has an 8-level priority, individually maskable, vectored interrupt controller, and drives the NIRQ and NFIRQ pins of the ARM7TDMI from:

- The external fast interrupt line (FIQ)
- The three external interrupt request lines (IRQ0 - IRQ2)
- The interrupt signals from the on-chip peripherals

The AIC is largely programmable, offering maximum flexibility, and its vectoring features reduce the real-time overhead in handling interrupts.

The AIC also features a spurious vector, which reduces spurious interrupt handling to a minimum, and a protect mode that facilitates the debug capabilities.

#### **PIO: Parallel IO Controller**

The AT91X40 Series has 32 programmable I/O lines. Six pins are dedicated as general-purpose I/O pins. Other I/O lines are multiplexed with an external signal of a peripheral to optimize the use of available package pins. The PIO controller enables generation of an interrupt on input change and insertion of a simple input glitch filter on any of the PIO pins.

#### **WD: Watchdog**

The Watchdog is built around a 16-bit counter, and is used to prevent system lock-up if the software becomes trapped in a deadlock. It can generate an internal reset or interrupt, or assert an active level on the dedicated pin NWDOVF. All programming registers are password-protected to prevent unintentional programming.

#### **SF: Special Function**

The AT91X40 Series provides registers that implement the following special functions.

- Chip identification
- RESET status
- Protect Mode
- Write protection for the AT91R40807 internal 128-Kbyte memory

## **User Peripherals**

#### **USART: Universal Synchronous/Asynchronous Receiver Transmitter**

The AT91X40 Series provides two identical, full-duplex, universal synchronous/asynchronous receiver/transmitters.

Each USART has its own baud rate generator, and two dedicated Peripheral Data Controller channels. The data format includes a start bit, up to 8 data bits, an optional programmable parity bit and up to 2 stop bits.

The USART also features a Receiver Timeout register, facilitating variable length Frame support when it is working with the PDC, and a Time Guard register, used when interfacing with slow remote equipment.

#### **TC: Timer Counter**

The AT91X40 Series features a Timer Counter block that includes three identical 16-bit timer counter channels. Each channel can be independently programmed to perform a wide range of functions, including frequency measurement, event counting, interval measurement, pulse generation, delay timing and pulse-width modulation.

The Timer Counter can be used in Capture or Waveform Mode, and all three counter channels can be started simultaneously and chained together.

## EBI: External Bus Interface

The EBI generates the signals that control the access to the external memory or peripheral devices. The EBI is fully-programmable and can address up to 64M bytes. It has eight chip selects and a 24-bit address bus, the upper four bits of which are multiplexed with a chip select.

The 16-bit data bus can be configured to interface with 8- or 16-bit external devices. Separate read and write control signals allow for direct memory and peripheral interfacing.

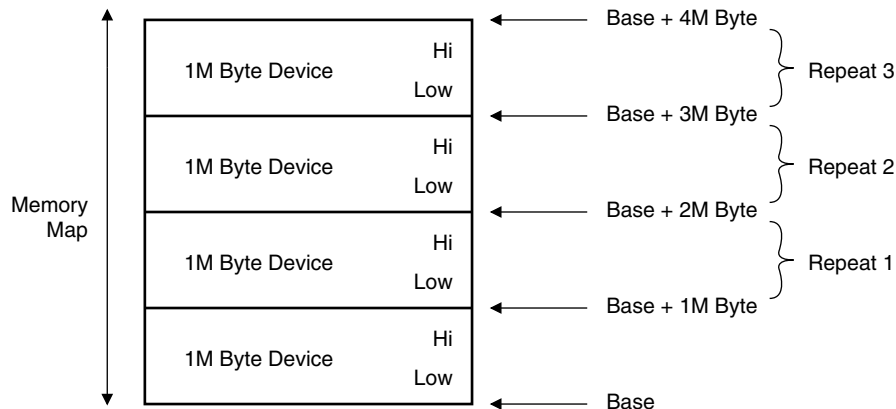

The EBI supports different access protocols allowing single-clock cycle memory accesses.

The main features are:

- External memory mapping
- Up to 8 chip select lines
- 8- or 16-bit data bus
- Byte write or byte select lines
- Remap of boot memory
- Two different read protocols
- Programmable wait state generation
- External wait request
- Programmable data float time

The “EBI User Interface” is described on page 35.

**Figure 6.** External Memory Smaller than Page Size

## External Memory Mapping

The memory map associates the internal 32-bit address space with the external 24-bit address bus.

The memory map is defined by programming the base address and page size of the external memories (see “EBI User Interface” registers EBI\_CSR0 to EBI\_CSR7). Note that A0 - A23 is only significant for 8-bit memory; A1 - A23 is used for 16-bit memory.

If the physical memory device is smaller than the programmed page size, it wraps around and appears to be repeated within the page. The EBI correctly handles any valid access to the memory device within the page (see Figure 6).

In the event of an access request to an address outside any programmed page, an Abort signal is generated. Two types of Abort are possible: instruction prefetch abort and data abort. The corresponding exception vector addresses are respectively 0x0000000C and 0x00000010. It is up to the system programmer to program the error handling routine to use in case of an Abort (see the ARM7TDMI datasheet for further information).

## External Bus Interface Pin Description

Name	Description	Type
A0 - A23	Address bus (output)	Output
D0 - D15	Data bus (input/output)	I/O
NCS0 - NCS3	Active low chip selects (output)	Output
CS4 - CS7	Active high chip selects (output)	Output
NRD	Read enable (output)	Output
NWR0 - NWR1	Lower and upper write enable (output)	Output
NOE	Output enable (output)	Output
NWE	Write enable (output)	Output
NUB, NLB	Upper and lower byte select (output)	Output
NWAIT	Wait request (input)	Input

The following table shows how certain EBI signals are multiplexed:

**Table 4.** EBI Signals

Multiplexed Signals		Functions
A23 - A20	CS4 - CS7	Allows from 4 to 8 chip select lines to be used
A0	NLB	8- or 16-bit data bus
NRD	NOE	Byte write or byte select access
NWR0	NWE	Byte write or byte select access
NWR1	NUB	Byte write or byte select access

## Chip Select Lines

The EBI provides up to eight chip select lines:

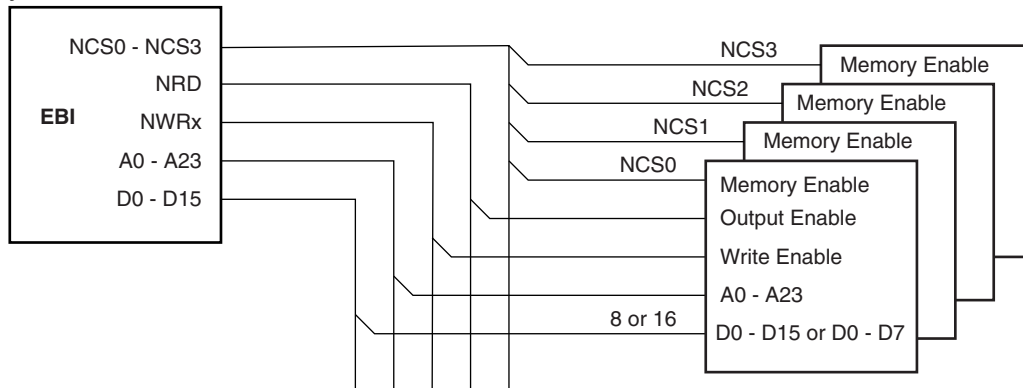

- Chip select lines NCS0 - NCS3 are dedicated to the EBI (not multiplexed).
- Chip select lines CS4 - CS7 are multiplexed with the top four address lines A23 - A20.

By exchanging address lines for chip select lines, the user can optimize the EBI to suit the external memory requirements: more external devices or larger address range for each device.

The selection is controlled by the ALE field in EBI\_MCR (Memory Control Register). The following combinations are possible:

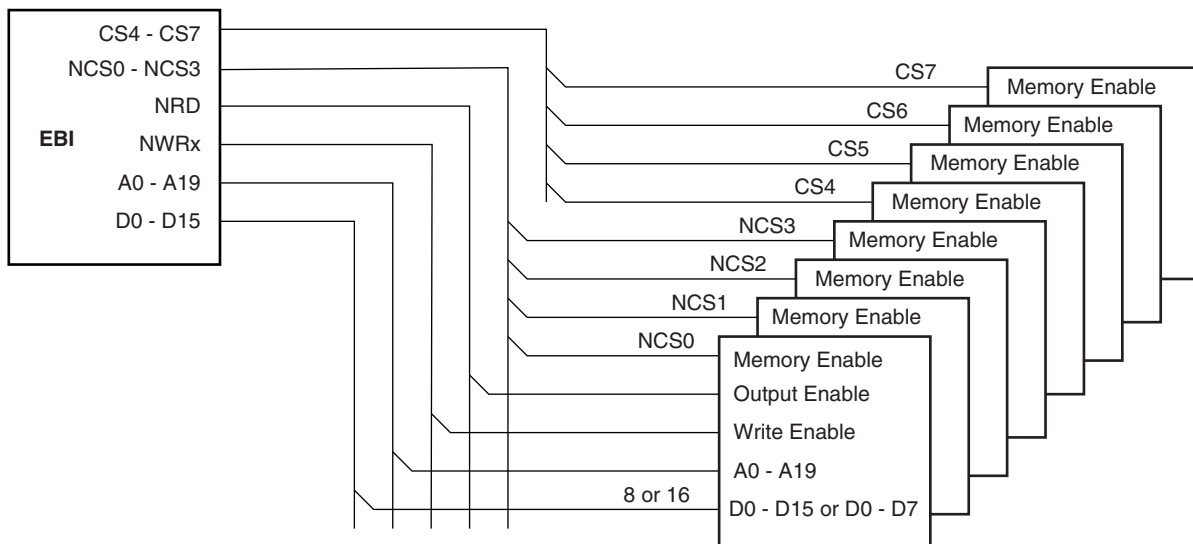

A20, A21, A22, A23 (configuration by default)  
 A20, A21, A22, CS4  
 A20, A21, CS5, CS4  
 A20, CS6, CS5, CS4  
 CS7, CS6, CS5, CS4

**Figure 7.** Memory Connections for Four External Devices

Note: For four external devices, the maximum address space per device is 16M bytes.

**Figure 8.** Memory Connections for Eight External Devices

Note: For eight external devices, the maximum address space per device is 1M byte.

## Data Bus Width

A data bus width of 8 or 16 bits can be selected for each chip select. This option is controlled by the DBW field in the EBI\_CSR (Chip Select Register) for the corresponding chip select.

Figure 9 shows how to connect a 512K x 8-bit memory on NCS2.

**Figure 9.** Memory Connection for an 8-Bit Data Bus

Figure 10 shows how to connect a 512K x 16-bit memory on NCS2.

**Figure 10.** Memory Connection for a 16-bit Data Bus

## Byte Write or Byte Select Access

Each chip select with a 16-bit data bus can operate with one of two different types of write access:

- Byte Write Access supports two byte write and a single read signal.
- Byte Select Access selects upper and/or lower byte with two byte select lines, and separate read and write signals.

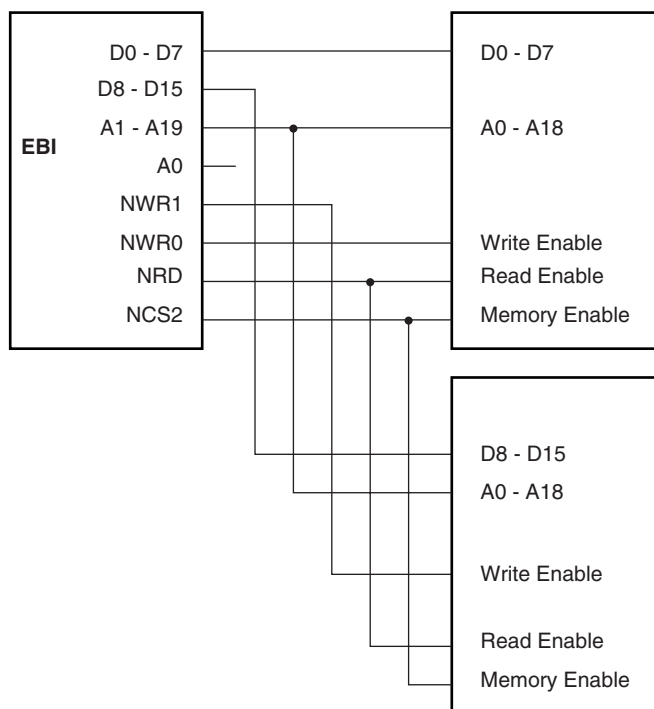

This option is controlled by the BAT field in the EBI\_CSR (Chip Select Register) for the corresponding chip select.

Byte Write Access is used to connect 2 x 8-bit devices as a 16-bit memory page.

- The signal A0/NLB is not used.
- The signal NWR1/NUB is used as NWR1 and enables upper byte writes.
- The signal NWR0/NWE is used as NWR0 and enables lower byte writes.
- The signal NRD/NOE is used as NRD and enables half-word and byte reads.

Figure 11 shows how to connect two 512K x 8-bit devices in parallel on NCS2.

**Figure 11.** Memory Connection for 2 x 8-bit Data Busses

Byte Select Access is used to connect 16-bit devices in a memory page.

- The signal A0/NLB is used as NLB and enables the lower byte for both read and write operations.
- The signal NWR1/NUB is used as NUB and enables the upper byte for both read and write operations.
- The signal NWR0/NWE is used as NWE and enables writing for byte or half word.
- The signal NRD/NOE is used as NOE and enables reading for byte or half word.

Figure 12 shows how to connect a 16-bit device with byte and half-word access (e.g. 16-bit SRAM) on NCS2.

**Figure 12.** Connection for a 16-Bit Data Bus with Byte and Half-word Access

Figure 13 shows how to connect a 16-bit device without byte access (e.g. Flash) on NCS2.

**Figure 13.** Connection for a 16-bit Data Bus without Byte Write Capability.

## Boot on NCS0

Depending on the device and the BMS pin level during the reset, the user can select either an 8-bit or 16-bit external memory device connected on NCS0 as the Boot Memory. In this case, EBI\_CSR0 (Chip Select Register 0) is reset at the following configuration for chip select 0:

- 8 wait states (WSE = 1, NWS = 7)
- 8-bit or 16-bit data bus width, depending on BMS

Byte access type and number of data float time are respectively set to Byte Write Access and 0. With a non-volatile memory interface, any values can be programmed for these parameters.

Before the remap command, the user can modify the chip select 0 configuration, programming the EBI\_CSR0 with exact boot memory characteristics. the base address becomes effective after the remap command, but the new number of wait states can be changed immediately. This is useful if a boot sequence needs to be faster.

## Read Protocols

The EBI provides two alternative protocols for external memory read access: standard and early read. The difference between the two protocols lies in the timing of the NRD (read cycle) waveform.

The protocol is selected by the DRP field in EBI\_MCR (Memory Control Register) and is valid for all memory devices. Standard read protocol is the default protocol after reset.

**Note:** In the following waveforms and descriptions, **NRD** represents NRD and NOE since the two signals have the same waveform. Likewise, **NWE** represents NWE, NWR0 and NWR1 unless NWR0 and NWR1 are otherwise represented. **ADDR** represents A0 - A23 and/or A1 - A23.

### Standard Read Protocol

Standard read protocol implements a read cycle in which NRD and NWE are similar. Both are active during the second half of the clock cycle. The first half of the clock cycle allows time to ensure completion of the previous access as well as the output of address and NCS before the read cycle begins.

During a standard read protocol, external memory access, NCS is set low and ADDR is valid at the beginning of the access while NRD goes low only in the second half of the master clock cycle to avoid bus conflict (see Figure 14). NWE is the same in both protocols. NWE always goes low in the second half of the master clock cycle (see Figure 15).

### Early Read Protocol

Early read protocol provides more time for a read access from the memory by asserting NRD at the beginning of the clock cycle. In the case of successive read cycles in the same memory, NRD remains active continuously. Since a read cycle normally limits the speed of operation of the external memory system, early read protocol can allow a faster clock frequency to be used. However, an extra wait state is required in some cases to avoid contentions on the external bus.

### Early Read Wait State

In early read protocol, an early read wait state is automatically inserted when an external write cycle is followed by a read cycle to allow time for the write cycle to end before the subsequent read cycle begins (see Figure 16). This wait state is generated in addition to any other programmed wait states (i.e. data float wait).

No wait state is added when a read cycle is followed by a write cycle, between consecutive accesses of the same type or between external and internal memory accesses.

Early read wait states affect the external bus only. They do not affect internal bus timing.

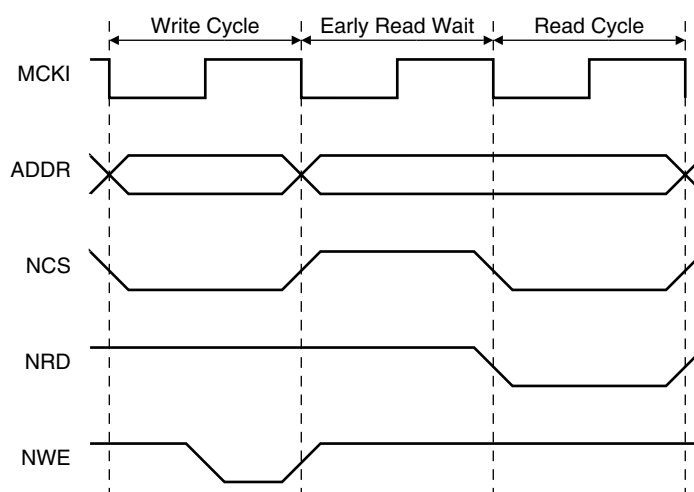

**Figure 14. Standard Read Protocol**

**Figure 15. Early Read Protocol**

**Figure 16. Early Read Wait State**

## Write Data Hold Time

During write cycles in both protocols, output data becomes valid after the falling edge of the NWE signal and remains valid after the rising edge of NWE, as illustrated in Figure 17. The external NWE waveform (on the NWE pin) is used to control the output data timing to guarantee this operation.

It is therefore necessary to avoid excessive loading of the NWE pins, which could delay the write signal too long and cause a contention with a subsequent read cycle in standard protocol.

**Figure 17.** Data Hold Time

In early read protocol the data can remain valid longer than in standard read protocol due to the additional wait cycle which follows a write access.

## Wait States

The EBI can automatically insert wait states. The different types of wait states are listed below:

- Standard wait states
- Data float wait states
- External wait states
- Chip select change wait states
- Early read wait states (see “Read Protocols” )

### Standard Wait States

Each chip select can be programmed to insert one or more wait states during an access on the corresponding device. This is done by setting the WSE field in the corresponding EBI\_CSR. The number of cycles to insert is programmed in the NWS field in the same register.

Below is the correspondence between the number of standard wait states programmed and the number of cycles during which the NWE pulse is held low:

0 wait states 1/2 cycle

1 wait state 1 cycle

For each additional wait state programmed, an additional cycle is added.

**Figure 18.** One Wait State Access

- Notes:
1. Early Read Protocol
  2. Standard Read Protocol

## Data Float Wait State

Some memory devices are slow to release the external bus. For such devices it is necessary to add wait states (data float waits) after a read access before starting a write access or a read access to a different external memory.

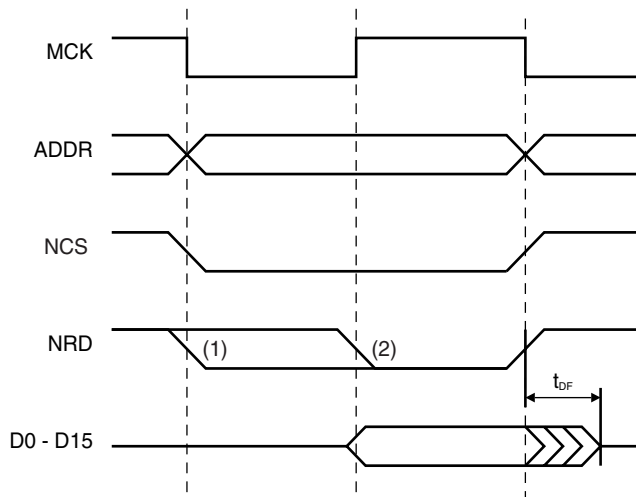

The Data Float Output Time ( $t_{DF}$ ) for each external memory device is programmed in the TDF field of the EBI\_CSR register for the corresponding chip select. The value (0 - 7 clock cycles) indicates the number of data float waits to be inserted and represents the time allowed for the data output to go high impedance after the memory is disabled.

Data float wait states do not delay internal memory accesses. Hence, a single access to an external memory with long  $t_{DF}$  will not slow down the execution of a program from internal memory.

The EBI keeps track of the programmed external data float time during internal accesses, to ensure that the external memory system is not accessed while it is still busy.

Internal memory accesses and consecutive accesses to the same external memory do not have added Data Float wait states.

**Figure 19.** Data Float Output Time

- Notes:
1. Early Read Protocol
  2. Standard Read Protocol

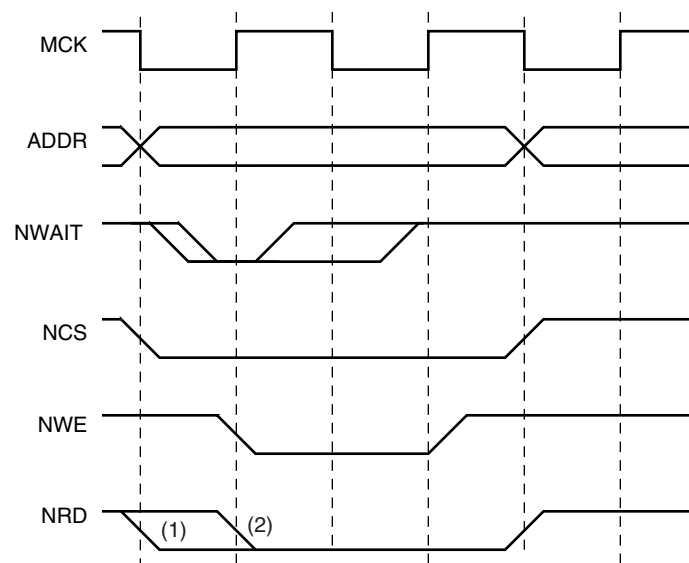

## External Wait

The NWAIT input can be used to add wait states at any time. NWAIT is active low and is detected on the rising edge of the clock.

If NWAIT is low at the rising edge of the clock, the EBI adds a wait state and changes neither the output signals nor its internal counters and state. When NWAIT is de-asserted, the EBI finishes the access sequence.

The NWAIT signal must meet setup and hold requirements on the rising edge of the clock.

**Figure 20.** External Wait

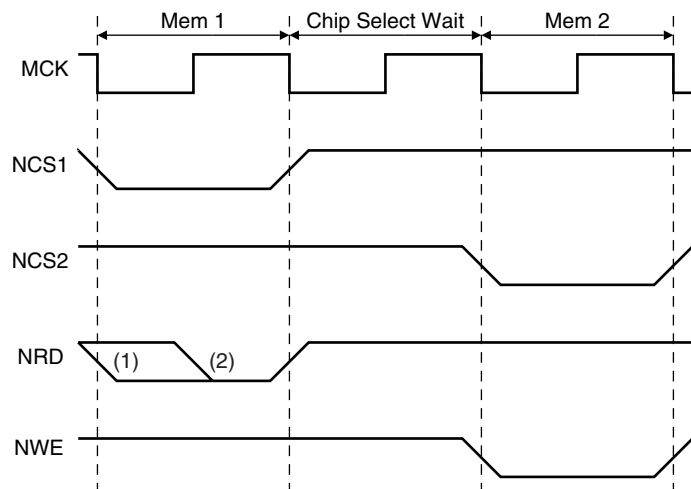

- Notes:
1. Early Read Protocol
  2. Standard Read Protocol

## Chip Select Change Wait States

A chip select wait state is automatically inserted when consecutive accesses are made to two different external memories (if no wait states have already been inserted). If any wait states have already been inserted, (e.g., data float wait) then none are added.

**Figure 21.** Chip Select Wait

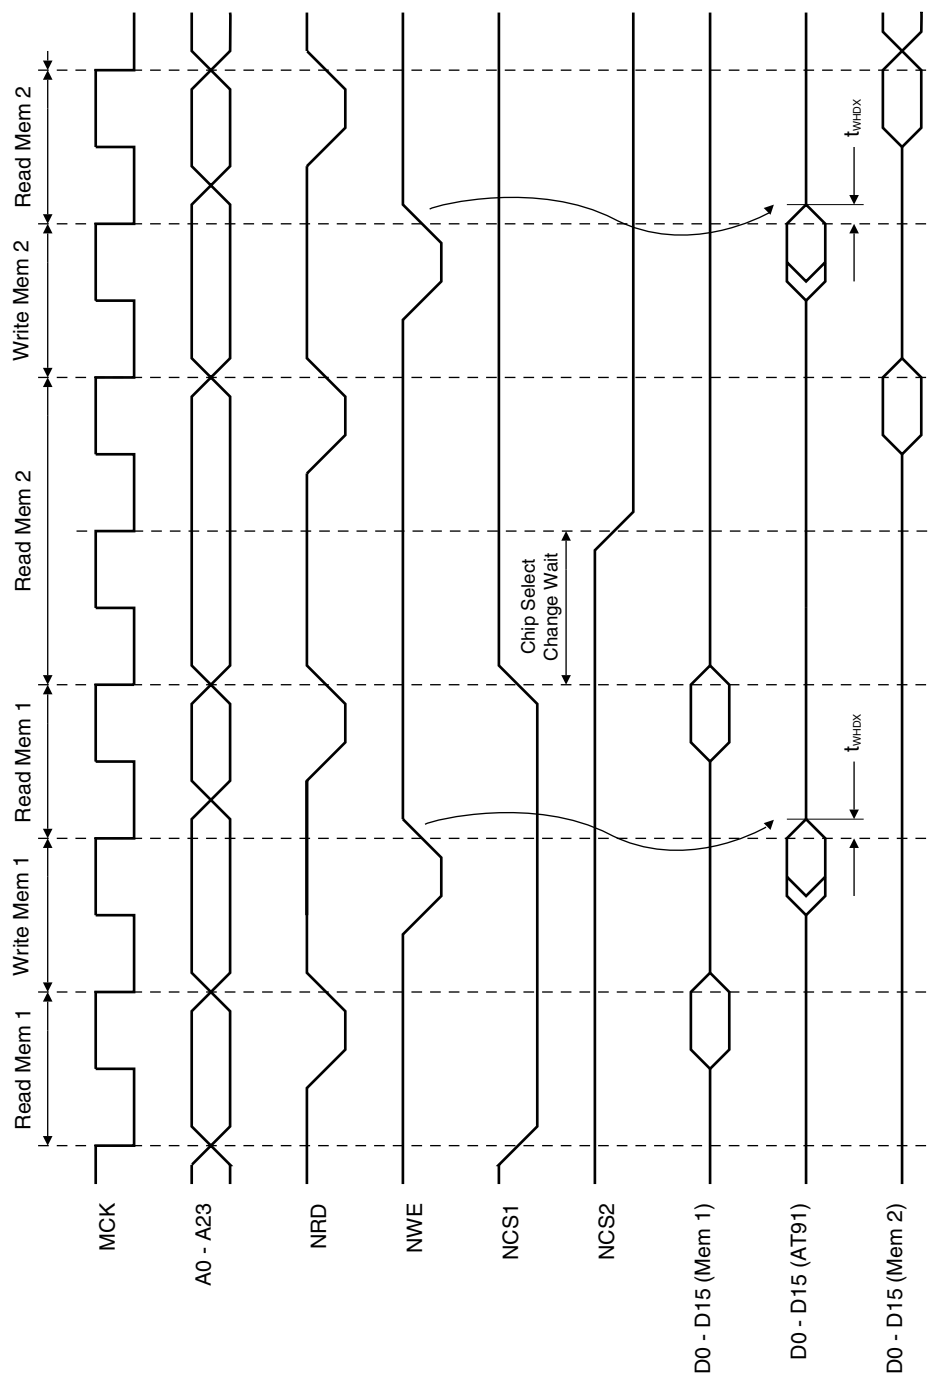

- Notes:
1. Early Read Protocol
  2. Standard Read Protocol

## Memory Access Waveforms

Figures 22 through 25 show examples of the two alternative protocols for external memory read access.

**Figure 22.** Standard Read Protocol without  $t_{DF}$

**Figure 23.** Early Read Protocol Without  $t_{DF}$

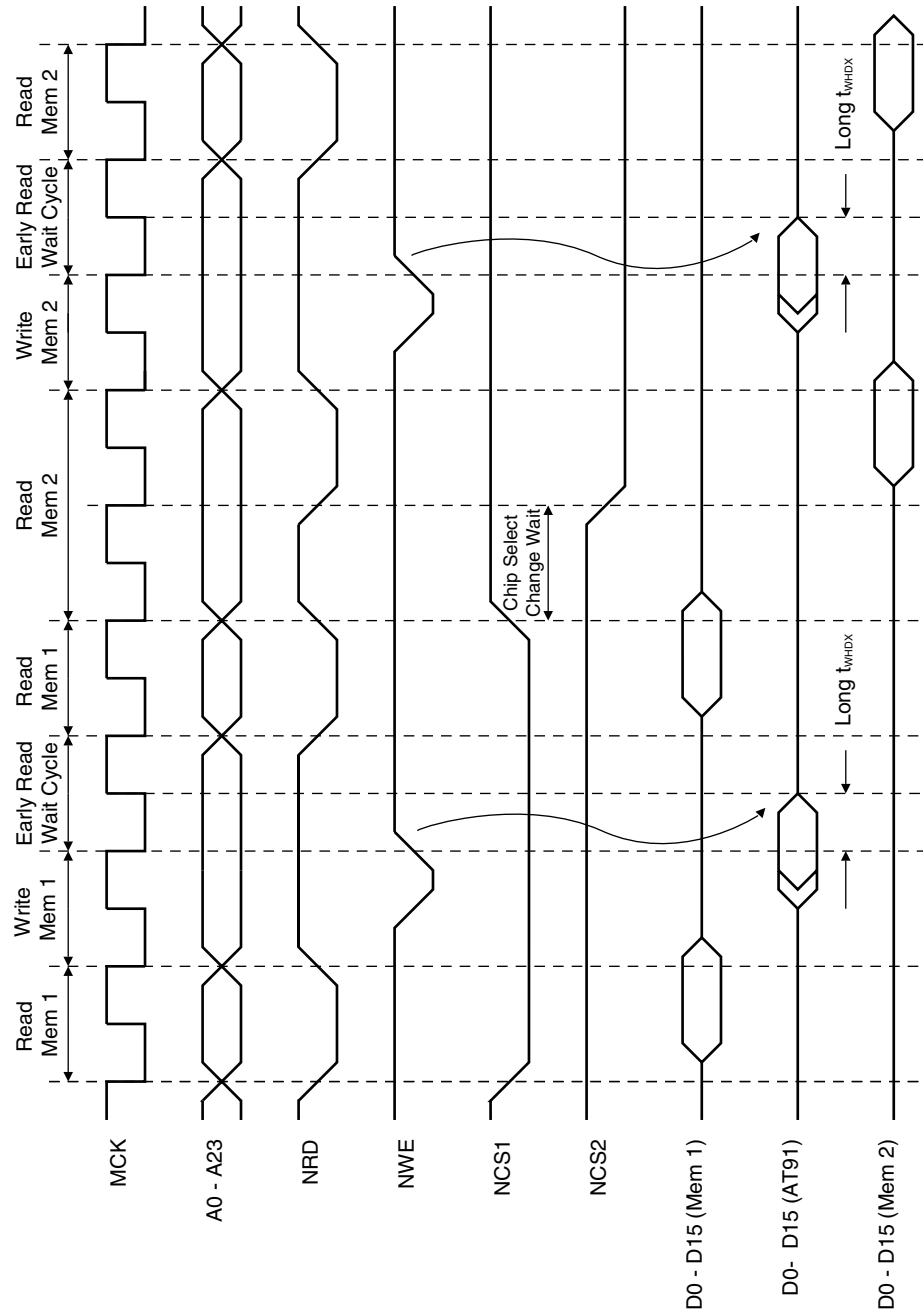

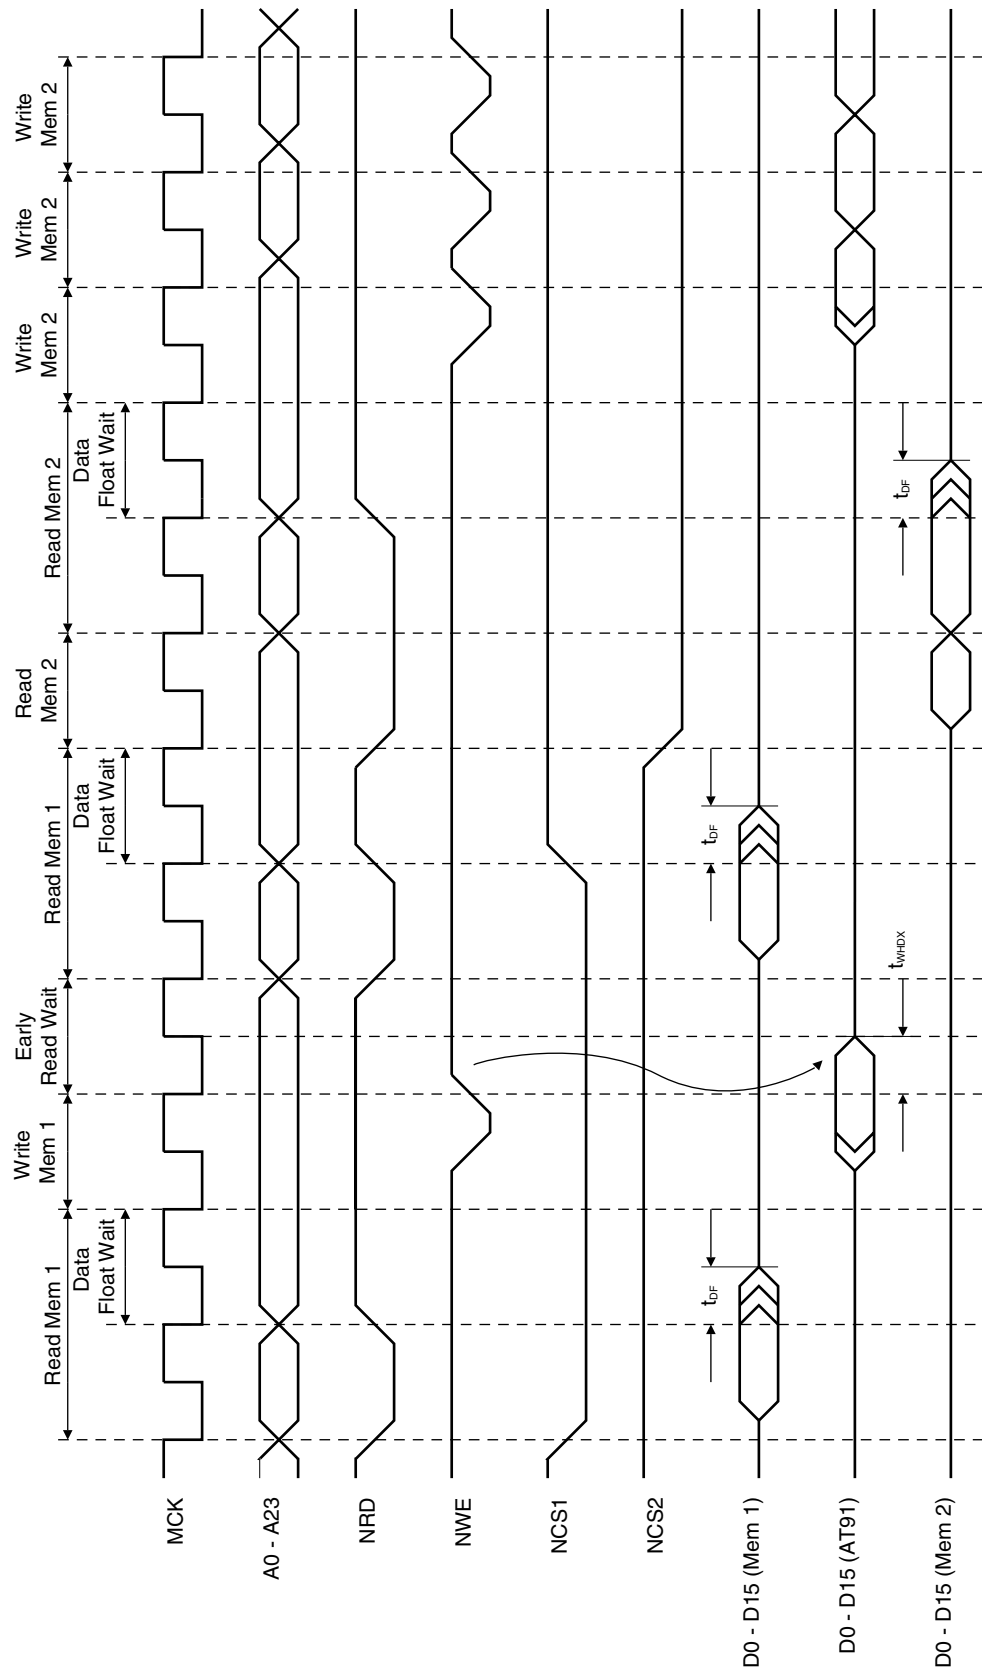

Figure 24. Standard Read Protocol with  $t_{DF}$

**Figure 25.** Early Read Protocol With  $t_{DF}$

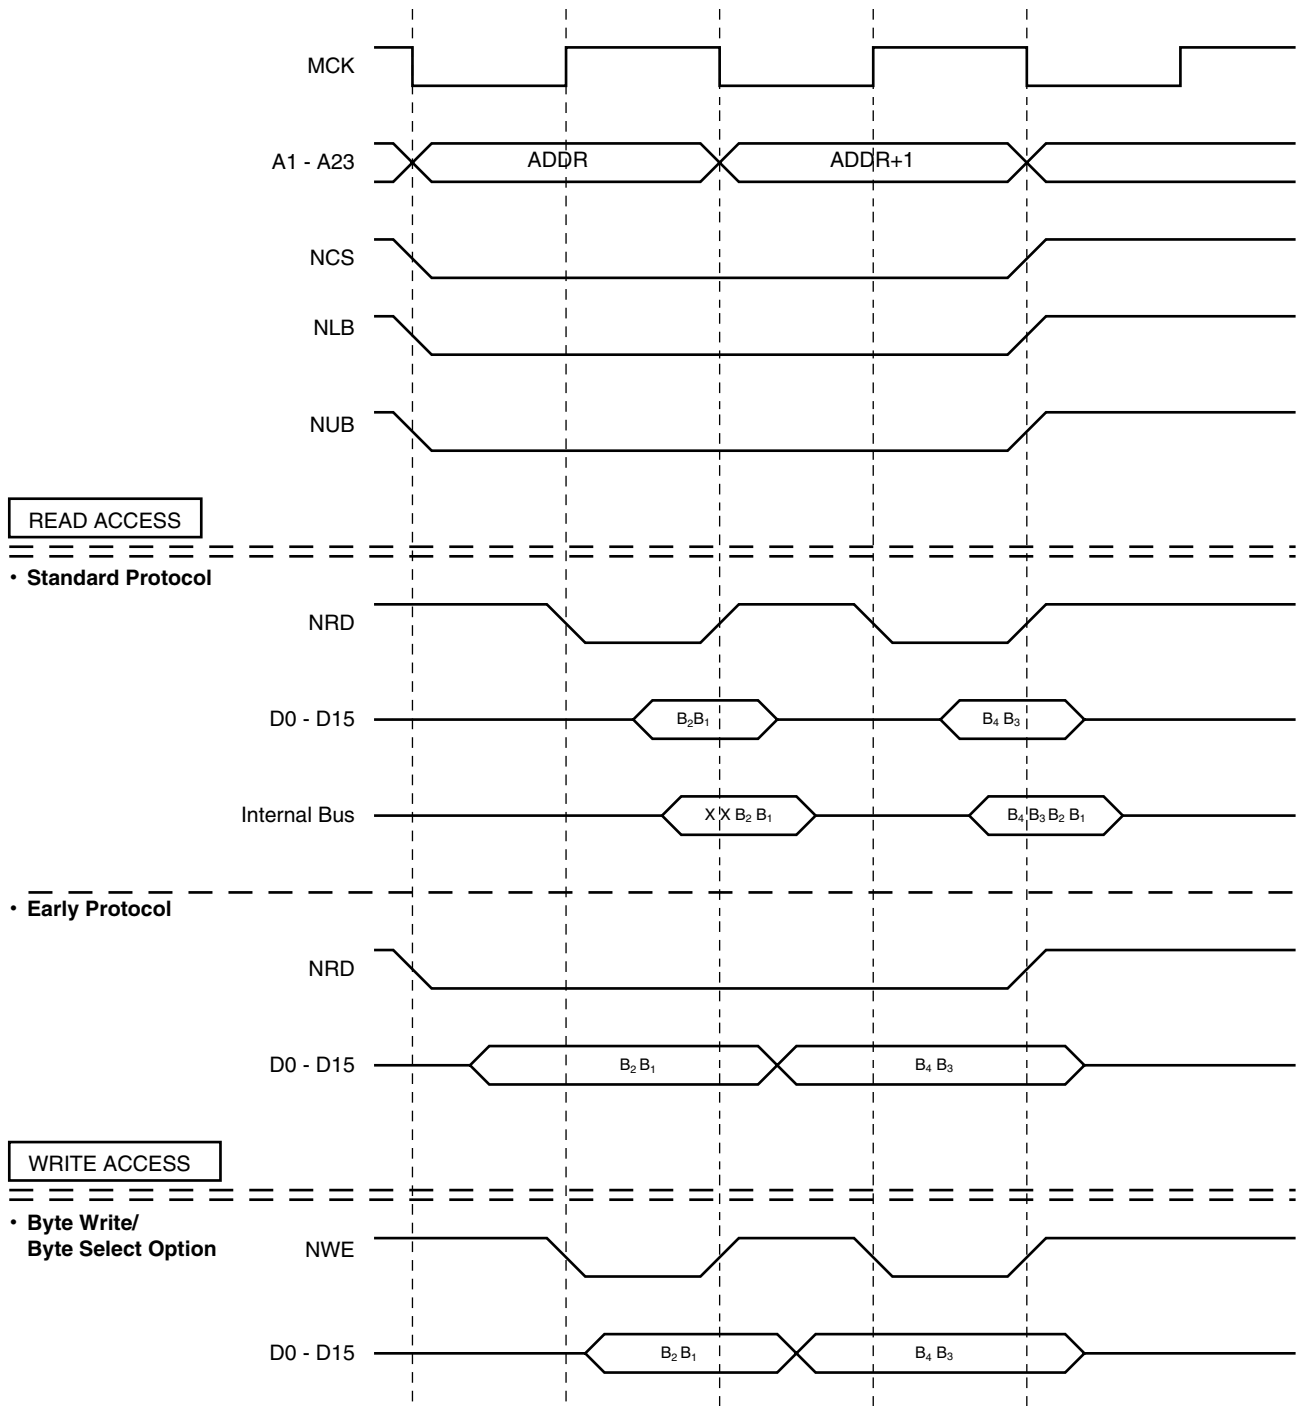

Figures 26 through 32 show the timing cycles and wait states for read and write access to the various AT91X40 Series external memory devices. The configurations described are shown in the following table:

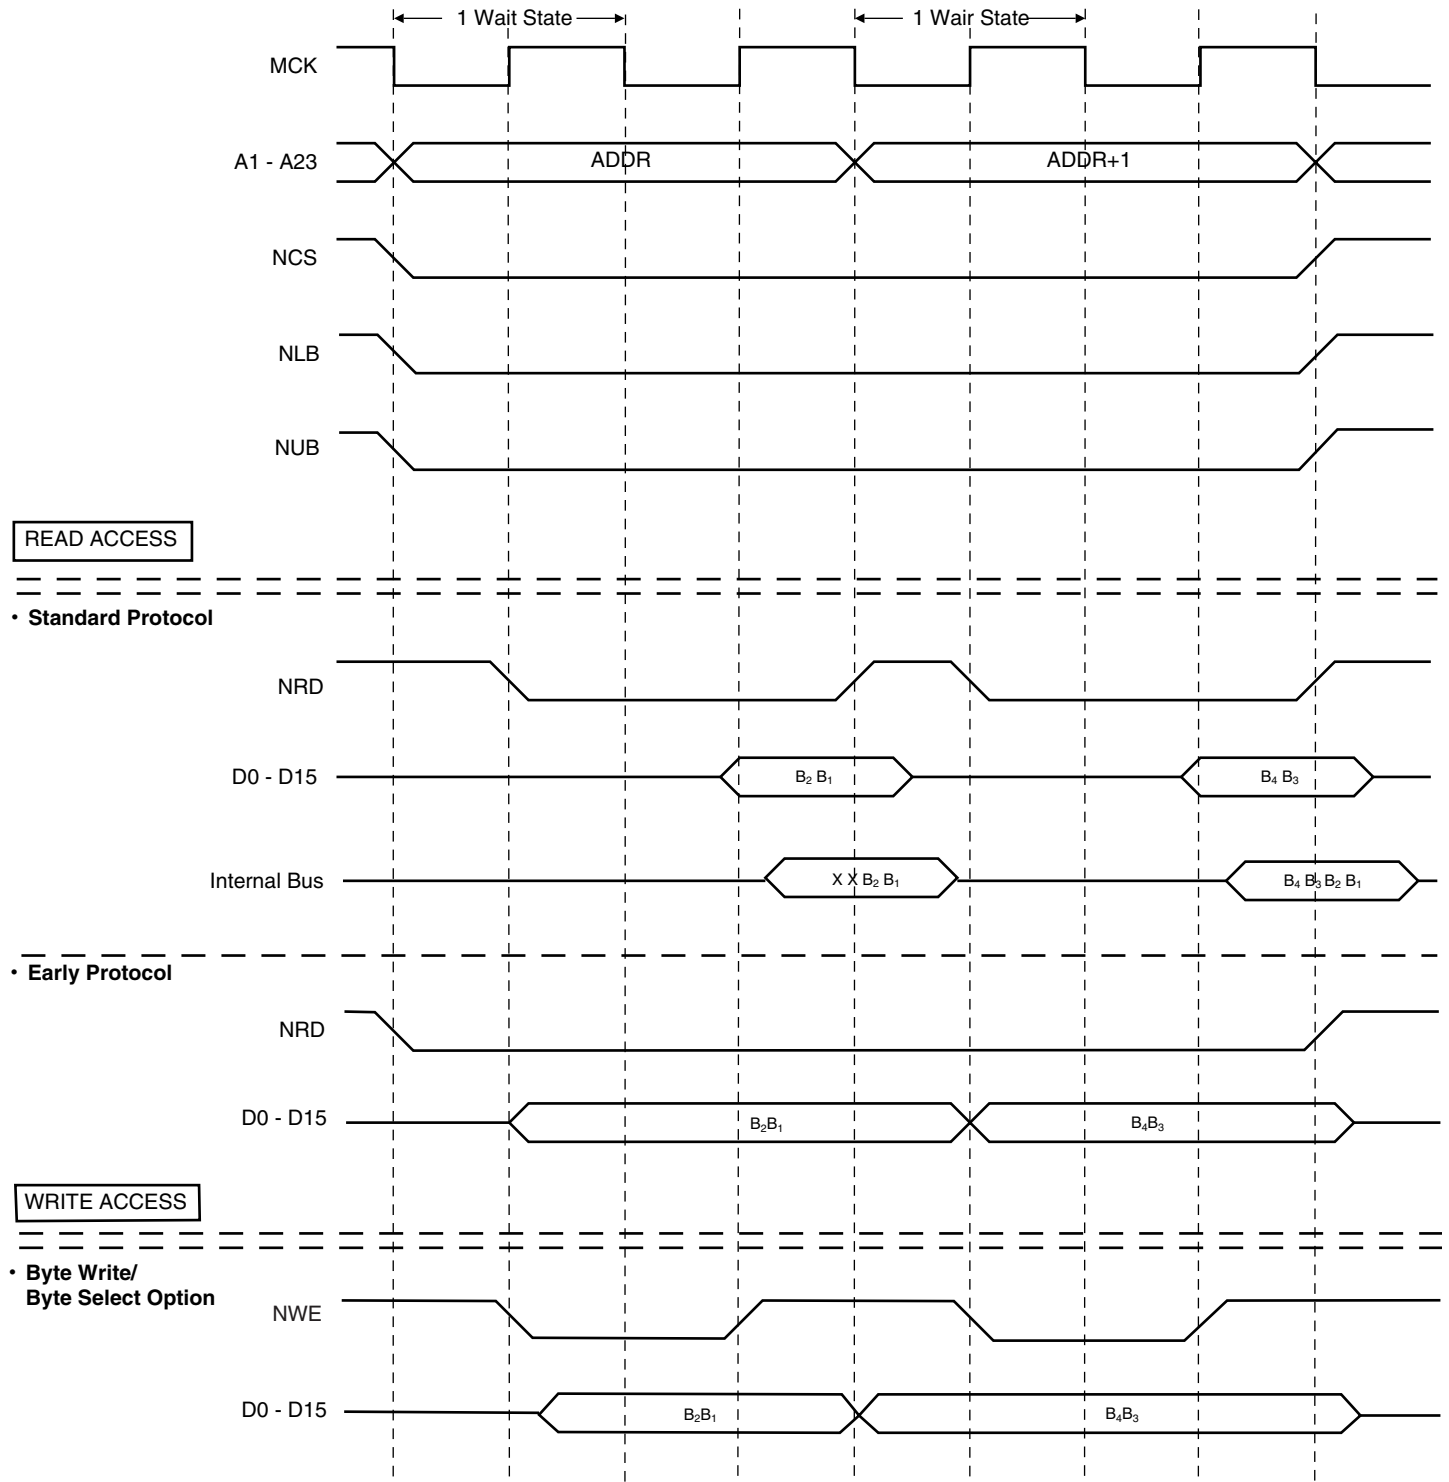

**Table 5.** Memory Access Waveforms

Figure Number	Number of Wait States	Bus Width	Size of Data Transfer
26	0	16	Word
27	1	16	Word
28	1	16	Half-word
29	0	8	Word

## EBI User Interface

The EBI is programmed using the registers listed in the table below. The Remap Control Register (EBI\_RCR) controls exit from Boot Mode (see “Boot on NCS0” on page 18) The Memory Control Register (EBI\_MCR) is used to program the number of active chip selects and data read

**Base Address:** 0xFFE00000

protocol. Eight Chip Select Registers (EBI\_CSR0 to EBI\_CSR7) are used to program the parameters for the individual external memories. Each EBI\_CSR must be programmed with a different base address, even for unused chip selects.

**Table 6.** EBI Memory Map

Offset	Register	Name	Access	Reset State
0x00	Chip Select Register 0	EBI_CSR0	Read/Write	0x0000203E <sup>(1)</sup> 0x0000203D <sup>(2)</sup>
0x04	Chip Select Register 1	EBI_CSR1	Read/Write	0x10000000
0x08	Chip Select Register 2	EBI_CSR2	Read/Write	0x20000000
0x0C	Chip Select Register 3	EBI_CSR3	Read/Write	0x30000000
0x10	Chip Select Register 4	EBI_CSR4	Read/Write	0x40000000

0x18	Chip Select Register 6	EBI_CSR6	Read/Write	0x60000000
0x1C	Chip Select Register 7	EBI_CSR7	Read/Write	0x70000000
0x20	Remap Control Register	EBI_RCR	Write only	–
0x24	Memory Control Register	EBI_MCR	Read/Write	0

Notes: 1. 8-bit boot (if BMS is detected high)  
2. 16-bit boot (if BMS is detected low)

## EBI Chip Select Register

**Register Name:** EBI\_CSR0 - EBI\_CSR7  
**Access Type:** Read/Write  
**Reset Value:** See Table 6  
**Absolute Address:** 0xFFE00000 - 0xFFE0001C  
**Offset:** 0x00 - 0x1C

31	30	29	28	27	26	25	24
BA							
23	22	21	20	19	18	17	16
BA				–	–	–	–
15	14	13	12	11	10	9	8
–	–	CSEN	BAT	TDF		PAGES	
7	6	5	4	3	2	1	0
PAGES	–	WSE	NWS		DBW		

- DBW: Data Bus Width**

DBW		Data Bus Width
0	0	Reserved
0	1	16-bit data bus width
1	0	8-bit data bus width
1	1	Reserved

- NWS: Number of Wait States**

This field is valid only if WSE is set.

NWS			Number of Standard Wait States
0	0	0	1
0	0	1	2
0	1	0	3
0	1	1	4
1	0	0	5
1	0	1	6
1	1	0	7
1	1	1	8

- WSE: Wait State Enable**

0 = Wait state generation is disabled. No wait states are inserted.  
 1 = Wait state generation is enabled.

- PAGES: Page Size**

PAGES		Page Size	Active Bits in Base Address
0	0	1M Byte	12 Bits (31 - 20)
0	1	4M Bytes	10 Bits (31 - 22)
1	0	16M Bytes	8 Bits (31 - 24)
1	1	64M Bytes	6 Bits (31 - 26)

- TDF: Data Float Output Time**

TDF			Number of Cycles Added after the Transfer
0	0	0	0
0	0	1	1
0	1	0	2
0	1	1	3
1	0	0	4
1	0	1	5
1	1	0	6
1	1	1	7

- BAT: Byte Access Type**

0 = Byte write access type.  
1 = Byte select access type.

- CSEN: Chip Select Enable**

0 = Chip select is disabled.  
1 = Chip select is enabled.

- BA: Base Address**

These bits contain the highest bits of the base address. If the page size is larger than 1M byte, the unused bits of the base address are ignored by the EBI decoder.

## EBI Remap Control Register

**Register Name:** EBI\_RCR  
**Access Type:** Write only  
**Absolute Address:** 0xFFE00020  
**Offset:** 0x20

31	30	29	28	27	26	25	24
–	–	–	–	–	–	–	–
23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8
–	–	–	–	–	–	–	–
7	6	5	4	3	2	1	0
–	–	–	–	–	–	–	RCB

- **RCB: Remap Command Bit**  
0 = No effect.  
1 = Cancels the remapping (performed at reset) of the page zero memory devices.

## EBI Memory Control Register

**Register Name:** EBI\_MCR  
**Access Type:** Read/Write  
**Reset Value:** 0  
**Absolute Address:** 0xFFE00024  
**Offset:** 0x24

31	30	29	28	27	26	25	24
–	–	–	–	–	–	–	–
23	22	21	20	19	18	17	16
–	–	–	–	–	–	–	–
15	14	13	12	11	10	9	8
–	–	–	–	–	–	–	–
7	6	5	4	3	2	1	0
–	–	–	DRP	–	ALE		

- **ALE: Address Line Enable**  
This field determines the number of valid address lines and the number of valid chip select lines.

ALE			Valid Address Bits	Maximum Addressable Space	Valid Chip Select
0	X	X	A20, A21, A22, A23	16M Bytes	None
1	0	0	A20, A21, A22	8M Bytes	CS4
1	0	1	A20, A21	4M Bytes	CS4, CS5
1	1	0	A20	2M Bytes	CS4, CS5, CS6
1	1	1	None	1M Byte	CS4, CS5, CS6, CS7

- **DRP: Data Read Protocol**  
0 = Standard read protocol for all external memory devices enabled.  
1 = Early read protocol for all external memory devices enabled.

## **PS: Power-saving**

The AT91X40 Series Power-saving feature enables optimization of power consumption. The PS controls the CPU and Peripheral Clocks. One control register (PS\_CR) enables the user to stop the ARM7TDMI Clock and enter Idle Mode. One set of registers with a set/clear mechanism enables and disables the peripheral clocks individually.

The ARM7TDMI clock is enabled after a reset and is automatically re-enabled by any enabled interrupt in the Idle Mode.

## **Peripheral Clocks**

The clock of each peripheral integrated in the AT91X40 Series can be individually enabled and disabled by writing to the Peripheral Clock Enable (PS\_PCER) and Peripheral Clock Disable Registers (PS\_PCDR). The status of the peripheral clocks can be read in the Peripheral Clock Status Register (PS\_PCSR).

When a peripheral clock is disabled, the clock is immediately stopped. When the clock is re-enabled, the peripheral resumes action where it left off.

To avoid data corruption or erroneous behavior of the system, the system software only disables the clock after all programmed peripheral operations have finished.

The peripheral clocks are automatically enabled after a reset.

The bits that control the peripheral clocks are the same as those that control the Interrupt Sources in the AIC.

## PS User Interface

Base Address: 0xFFFF4000

**Table 7.** PS Memory Map

Offset	Register	Name	Access	Reset State
0x00	Control Register	PS_CR	Write only	–

 0 = Timer Counter 2 clock is disabled.  
 1 = Timer Counter 2 clock is enabled.
- PIO: Parallel IO Clock Status**  
 0 = Parallel IO clock is disabled.  
 1 = Parallel IO clock is enabled.

## AIC: Advanced Interrupt Controller

The AT91X40 Series has an 8-level priority, individually maskable, vectored interrupt controller. This feature substantially reduces the software and real-time overhead in handling internal and external interrupts.

The interrupt controller is connected to the NFIQ (fast interrupt request) and the NIRQ (standard interrupt request) inputs of the ARM7TDMI processor. The processor's NFIQ line can only be asserted by the external fast interrupt request input: FIQ. The NIRQ line can be asserted by the

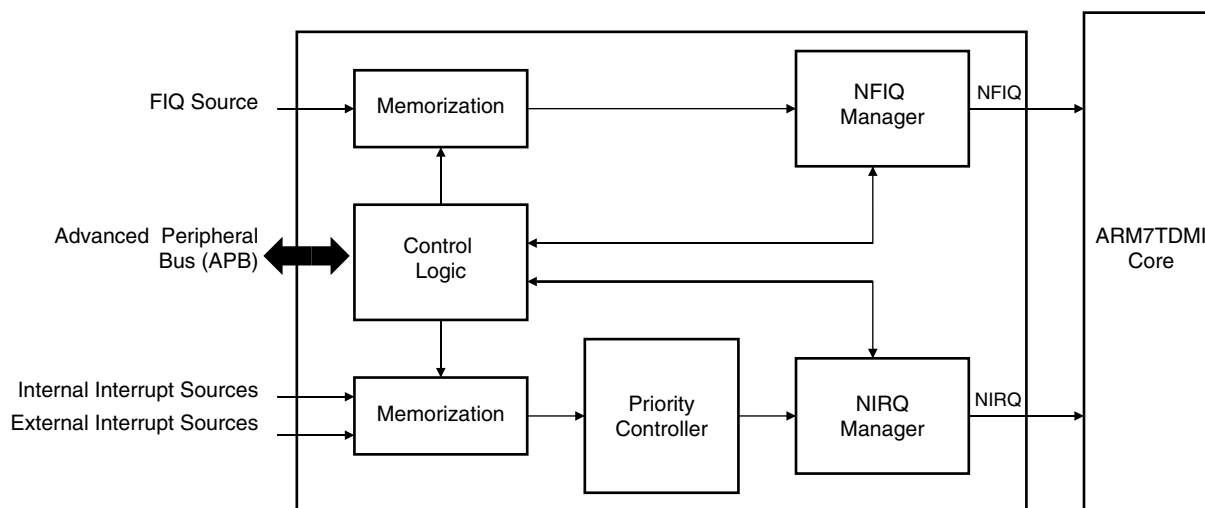

interrupts generated by the on-chip peripherals and the external interrupt request lines: IRQ0 to IRQ2.

The 8-level priority encoder allows the customer to define the priority between the different NIRQ interrupt sources.

Internal sources are programmed to be level sensitive or edge triggered. External sources can be programmed to be positive or negative edge triggered or high- or low-level sensitive.

The interrupt sources are listed in Table 8 and the AIC programmable registers in Table 9.

**Figure 33.** Interrupt Controller Block Diagram

**Note:** After a hardware reset, the AIC pins are controlled by the PIO Controller. They must be configured to be controlled by the peripheral before being used.

**Table 8.** AIC Interrupt Sources

Interrupt Source <sup>(1)</sup>	Interrupt Name	Interrupt Description
0	FIQ	Fast Interrupt
1	SWIRQ	Software Interrupt
2	US0IRQ	USART Channel 0 interrupt

Notes: 1. Reserved interrupt sources are not available. Corresponding registers must not be used and read 0.

## Hardware Interrupt Vectoring

The hardware interrupt vectoring reduces the number of instructions to reach the interrupt handler to only one. By storing the following instruction at address 0x00000018, the processor loads the program counter with the interrupt handler address stored in the AIC\_IVR register. Execution is then vectored to the interrupt handler corresponding to the current interrupt.

```
ldr PC,[PC,# - &F20]
```

The current interrupt is the interrupt with the highest priority when the Interrupt Vector Register (AIC\_IVR) is read. The value read in the AIC\_IVR corresponds to the address stored in the Source Vector Register (AIC\_SVR) of the current interrupt. Each interrupt source has its corresponding AIC\_SVR. In order to take advantage of the hardware interrupt vectoring it is necessary to store the address of each interrupt handler in the corresponding AIC\_SVR, at system initialization.

## Priority Controller

The NIRQ line is controlled by an 8-level priority encoder. Each source has a programmable priority level of 7 to 0. Level 7 is the highest priority and level 0 the lowest.

When the AIC receives more than one unmasked interrupt at a time, the interrupt with the highest priority is serviced first. If both interrupts have equal priority, the interrupt with the lowest interrupt source number (see table 8) is serviced first.

The current priority level is defined as the priority level of the current interrupt at the time the register AIC\_IVR is read (the interrupt which will be serviced).

In the case when a higher priority unmasked interrupt occurs while an interrupt already exists, there are two possible outcomes depending on whether the AIC\_IVR has been read.

- If the NIRQ line has been asserted but the AIC\_IVR has not been read, then the processor will read the new higher priority interrupt handler address in the AIC\_IVR register and the current interrupt level is updated.
- If the processor has already read the AIC\_IVR then the NIRQ line is reasserted. When the processor has authorized nested interrupts to occur and reads the AIC\_IVR again, it reads the new, higher priority interrupt handler address. At the same time the current priority value is pushed onto a first-in last-out stack and the current priority is updated to the higher priority.

When the end of interrupt command register (AIC\_EOICR) is written the current interrupt level is updated with the last stored interrupt level from the stack (if any). Hence at the end of a higher priority interrupt, the AIC returns to the pre-

vious state corresponding to the preceding lower priority interrupt which had been interrupted.

## Interrupt Handling

The interrupt handler must read the AIC\_IVR as soon as possible. This de-asserts the NIRQ request to the processor and clears the interrupt in case it is programmed to be edge triggered. This permits the AIC to assert the NIRQ line again when a higher priority unmasked interrupt occurs.

At the end of the interrupt service routine, the end of interrupt command register (AIC\_EOICR) must be written. This allows pending interrupts to be serviced.

## Interrupt Masking

Each interrupt source, including FIQ, can be enabled or disabled using the command registers AIC\_IECR and AIC\_IDCR. The interrupt mask can be read in the read only register AIC\_IMR. A disabled interrupt does not affect the servicing of other interrupts.

## Interrupt Clearing and Setting

All interrupt sources which are programmed to be edge triggered (including FIQ) can be individually set or cleared by respectively writing to the registers AIC\_ISCR and AIC\_ICCR. This function of the interrupt controller is available for auto-test or software debug purposes.

## Fast Interrupt Request

The external FIQ line is the only source which can raise a fast interrupt request to the processor. Therefore, it has no priority controller.

The external FIQ line can be programmed to be positive or negative edge triggered or high- or low-level sensitive in the AIC\_SMR0 register.

The fast interrupt handler address can be stored in the AIC\_SVR0 register. The value written into this register is available by reading the AIC\_FVR register when an FIQ interrupt is raised. By storing the following instruction at address 0x0000001C, the processor will load the program counter with the interrupt handler address stored in the AIC\_FVR register.

```
ldr PC,[PC,# -&F20]
```

Alternatively the interrupt handler can be stored starting from address 0x0000001C as described in the ARM7TDMI datasheet.

## Software Interrupt

Interrupt source 1 of the advanced interrupt controller is a software interrupt. It must be programmed to be edge trig-

gered in order to set or clear it by writing to the AIC\_ISCR and AIC\_ICCR.

This is totally independent of the SWI instruction of the ARM7TDMI processor.

## Spurious Interrupt

When the AIC asserts the NIRQ line, the ARM7TDMI enters IRQ Mode and the interrupt handler reads the IVR. It may happen that the AIC de-asserts the NIRQ line after the core has taken into account the NIRQ assertion and before the read of the IVR.

This behavior is called a Spurious Interrupt.

The AIC is able to detect these Spurious Interrupts and returns the Spurious Vector when the IVR is read. The Spurious Vector can be programmed by the user when the vector table is initialized.

A spurious interrupt may occur in the following cases:

- With any sources programmed to be level sensitive, if the interrupt signal of the AIC input is de-asserted at the same time as it is taken into account by the ARM7TDMI.
- If an interrupt is asserted at the same time as the software is disabling the corresponding source through AIC\_IDCR (this can happen due to the pipelining of the ARM core).

The same mechanism of spurious interrupt occurs if the ARM7TDMI reads the IVR (application software or ICE) when there is no interrupt pending. This mechanism is also valid for the FIQ interrupts.

Once the AIC enters the spurious interrupt management, it asserts neither the NIRQ nor the NFIQ lines to the ARM7TDMI as long as the spurious interrupt is not acknowledged. Therefore, it is mandatory for the Spurious Interrupt Service Routine to acknowledge the “spurious” behavior by writing to the AIC\_EOICR (End of Interrupt) before returning to the interrupted software. It also can perform other operation(s), e.g., trace possible undesirable behavior.

## Protect Mode

The Protect Mode permits reading of the Interrupt Vector Register without performing the associated automatic operations. This is necessary when working with a debug system.

When a Debug Monitor or an ICE reads the AIC User Interface, the IVR could be read. This would have the following consequences in Normal Mode.

- If an enabled interrupt with a higher priority than the current one is pending, it would be stacked
- If there is no enabled pending interrupt, the spurious vector would be returned

In either case, an End of Interrupt command would be necessary to acknowledge and to restore the context of the AIC. This operation is generally not performed by the debug system. Hence the debug system would become strongly intrusive, and could cause the application to enter an undesired state.

This is avoided by using Protect Mode.

The Protect Mode is enabled by setting the AIC bit in the SF Protect Mode Register (see SF: Special Function Registers on page 80).

When Protect Mode is enabled, the AIC performs interrupt stacking only when a write access is performed on the AIC\_IVR. Therefore, the Interrupt Service Routines must write (arbitrary data) to the AIC\_IVR just after reading it.

The new context of the AIC, including the value of the Interrupt Status Register (AIC\_ISR), is updated with the current interrupt only when IVR is written.

An AIC\_IVR read on its own (e.g. by a debugger), modifies neither the AIC context nor the AIC\_ISR.

Extra AIC\_IVR reads performed in between the read and the write can cause unpredictable results. Therefore, it is strongly recommended not to set a breakpoint between these 2 actions, nor to stop the software.

The debug system must not write to the AIC\_IVR as this would cause undesirable effects.

The following table shows the main steps of an interrupt and the order in which they are performed according to the mode:

Action	Normal Mode	Protect Mode
Calculate active interrupt (higher than current or spurious)	Read AIC_IVR	Read AIC_IVR
Determine and return the vector of the active interrupt	Read AIC_IVR	Read AIC_IVR
Memorize interrupt	Read AIC_IVR	Read AIC_IVR
Push on internal stack the current priority level	Read AIC_IVR	Write AIC_IVR
Acknowledge the interrupt <sup>(1)</sup>	Read AIC_IVR	Write AIC_IVR
No effect <sup>(2)</sup>	Write AIC_IVR	—

- Notes:
1. NIRQ de-assertion and automatic interrupt clearing if the source is programmed as level sensitive.
  2. Software that has been written and debugged using Protect Mode will run correctly in Normal Mode without modification. However, in Normal Mode the AIC\_IVR write has no effect and can be removed to optimize the code.

## AIC User Interface

Base Address: 0xFFFFF000

**Table 9.** AIC Memory Map

Offset	Register	Name	Access	Reset State

## AIC Source Mode Register

**Register Name:** AIC\_SMR0 - AIC\_SMR31

**Access Type:** Read/Write

**Reset Value:** 0

**Offset:** 0x000 - 0x07C

31	30	29	28	27	26	25	24
—	—	—	—	—	—	—	—
23	22	21	20	19	18	17	16
—	—	—	—	—	—	—	—
15	14	13	12	11	10	9	8
—	—	—	—	—	—	—	—
7	6	5	4	3	2	1	0
—	SRCTYPE		—	—	PRIOR		

- **PRIOR: Priority Level**

Program the priority level for all sources except source 0 (FIQ).

The priority level can be between 0 (lowest) and 7 (highest).

The priority level is not used for the FIQ, in the SMR0.

- **SRCTYPE: Interrupt Source Type**

Program the input to be positive or negative edge triggered or positive or negative level sensitive.

The active level or edge is not programmable for the internal sources.

SRCTYPE		Internal Sources	External Sources
0	0	Level Sensitive	Low Level Sensitive
0	1	Edge Triggered	Negative Edge Triggered
1	0	Level Sensitive	High Level Sensitive
1	1	Edge Triggered	Positive Edge Triggered

## AIC Source Vector Register

**Register Name:** AIC\_SVR0 - AIC\_SVR31  
**Access Type:** Read/Write  
**Reset Value:** 0  
**Offset:** 0x080 - 0x0FC

31	30	29	28	27	26	25	24
VECTOR							
23	22	21	20	19	18	17	16
VECTOR							
15	14	13	12	11	10	9	8
VECTOR							
7	6	5	4	3	2	1	0
VECTOR							

- VECTOR: Interrupt Handler Address**

The user may store in these registers the addresses of the corresponding handler for each interrupt source.

## AIC Interrupt Vector Register

**Register Name:** AIC\_IVR  
**Access Type:** Read only  
**Reset Value:** 0  
**Offset:** 0x100

31	30	29	28	27	26	25	24
IRQV							
23	22	21	20	19	18	17	16
IRQV							
15	14	13	12	11	10	9	8
IRQV							
7	6	5	4	3	2	1	0
IRQV							

- IRQV: Interrupt Vector Register**

The IRQ Vector Register contains the vector programmed by the user in the Source Vector Register corresponding to the current interrupt.

The Source Vector Register (1 to 31) is indexed using the current interrupt number when the Interrupt Vector Register is read.

When there is no current interrupt, the IRQ Vector Register reads 0.

## AIC FIQ Vector Register

**Register Name:** AIC\_FVR  
**Access Type:** Read only  
**Reset Value:** 0  
**Offset:** 0x104

31	30	29	28	27	26	25	24
FIQV							
23	22	21	20	19	18	17	16
FIQV							
15	14	13	12	11	10	9	8
FIQV							
7	6	5	4	3	2	1	0
FIQV							

- FIQV: FIQ Vector Register**

The FIQ Vector Register contains the vector programmed by the user in the Source Vector Register 0 which corresponds to FIQ.

## AIC Interrupt Status Register

**Register Name:** AIC\_ISR  
**Access Type:** Read only  
**Reset Value:** 0  
**Offset:** 0x108

31	30	29	28	27	26	25	24
–	–	–	–	–	–	–	–
23	22	21	20	19	18	17	16
–	–	–	–	–	–	–	–
15	14	13	12	11	10	9	8
–	–	–	–	–	–	–	–
7	6	5	4	3	2	1	0
–	–	–	IRQID				

- **IRQID: Current IRQ Identifier**  
The Interrupt Status Register returns the current interrupt source number.

## AIC Interrupt Pending Register

**Register Name:** AIC\_IPR  
**Access Type:** Read only  
**Reset Value:** 0  
**Offset:** 0x10C

31	30	29	28	27	26	25	24
–	–	–	–	–	–	–	–
23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8
–	–	–	–	–	–	–	PIOIRQ
7	6	5	4	3	2	1	0
WDIRQ	TC2IRQ	TC1IRQ	TC0IRQ	US1IRQ	US0IRQ	SWIRQ	FIQ

- **Interrupt Pending**  
0 = Corresponding interrupt is inactive.  
1 = Corresponding interrupt is pending.

## AIC Interrupt Mask Register

**Register Name:** AIC\_IMR  
**Access Type:** Read only  
**Reset Value:** 0  
**Offset:** 0x110

31	30	29	28	27	26	25	24
–	–	–	–	–	–	–	–
23	22	21	20	19	18	17	16
–	–	–	–	–	IRQ2	IRQ1	IRQ0
15	14	13	12	11	10	9	8
–	–	–	–	–	–	–	PIOIRQ
7	6	5	4	3	2	1	0
WDIRQ	TC2IRQ	TC1IRQ	TC0IRQ	US1IRQ	US0IRQ	SWIRQ	FIQ

- **Interrupt Mask**  
0 = Corresponding interrupt is disabled.  
1 = Corresponding interrupt is enabled.

## AIC Core Interrupt Status Register

**Register Name:** AIC\_CISR

**Access Type:** Read only

**Reset Value:** 0

**Offset:** 0x114

31	30	29	28	27	26	25	24
–	–	–	–	–	–	–	–
23	22	21	20	19	18	17	16
–	–	–	–	–	–	–	–
15	14	13	12	11	10	9	8
–	–	–	–	–	–	–	–
7	6	5	4	3	2	1	0
–	–	–	–	–	–	NIRQ	NFIQ

- **NFIQ: NFIQ Status**  
0 = NFIQ line inactive.  
1 = NFIQ line active.
- **NIRQ: NIRQ Status**  
0 = NIRQ line inactive.  
1 = NIRQ line active.

## AIC Interrupt Enable Command Register

**Register Name:** AIC\_IECR

**Access Type:** Write only

**Offset:** 0x120

31	30	29	28	27	26	25	24
–	–	–	–	–	–	–	–
23	22	21	20	19	18	17	16
–	–	–	–	–	IRQ2	IRQ1	IRQ0
15	14	13	12	11	10	9	8
–	–	–	–	–	–	–	PIOIRQ
7	6	5	4	3	2	1	0
WDIRQ	TC2IRQ	TC1IRQ	TC0IRQ	US1IRQ	US0IRQ	SWIRQ	FIQ

- Interrupt Enable**

0 = No effect.

1 = Enables corresponding interrupt.

## AIC Interrupt Disable Command Register

**Register Name:** AIC\_IDCR

**Access Type:** Write only

**Offset:** 0x124

31	30	29	28	27	26	25	24
–	–	–	–	–	–	–	–
23	22	21	20	19	18	17	16
–	–	–	–	–	IRQ2	IRQ1	IRQ0
15	14	13	12	11	10	9	8
–	–	–	–	–	–	–	PIOIRQ
7	6	5	4	3	2	1	0
WDIRQ	TC2IRQ	TC1IRQ	TC0IRQ	US1IRQ	US0IRQ	SWIRQ	FIQ

- Interrupt Disable**

0 = No effect.

1 = Disables corresponding interrupt.

## AIC Interrupt Clear Command Register

**Register Name:** AIC\_ICCR

**Access Type:** Write only

**Offset:** 0x128

31	30	29	28	27	26	25	24
—	—	—	—	—	—	—	—
23	22	21	20	19	18	17	16
—	—	—	—	—	IRQ2	IRQ1	IRQ0
15	14	13	12	11	10	9	8
—	—	—	—	—	—	—	PIOIRQ
7	6	5	4	3	2	1	0
WDIRQ	TC2IRQ	TC1IRQ	TC0IRQ	US1IRQ	US0IRQ	SWIRQ	FIQ

- Interrupt Clear**

0 = No effect.

1 = Clears corresponding interrupt.

## AIC Interrupt Set Command Register

**Register Name:** AIC\_ISCR

**Access Type:** Write only

**Offset:** 0x12C

31	30	29	28	27	26	25	24
—	—	—	—	—	—	—	—
23	22	21	20	19	18	17	16
—	—	—	—	—	IRQ2	IRQ1	IRQ0
15	14	13	12	11	10	9	8
—	—	—	—	—	—	—	PIOIRQ
7	6	5	4	3	2	1	0
WDIRQ	TC2IRQ	TC1IRQ	TC0IRQ	US1IRQ	US0IRQ	SWIRQ	FIQ

- Interrupt Set**

0 = No effect.

1 = Sets corresponding interrupt.

## AIC End of Interrupt Command Register

**Register Name:** AIC\_EOICR

**Access Type:** Write only

**Offset:** 0x130

31	30	29	28	27	26	25	24
–	–	–	–	–	–	–	–
23	22	21	20	19	18	17	16
–	–	–	–	–	–	–	–
15	14	13	12	11	10	9	8
–	–	–	–	–	–	–	–
7	6	5	4	3	2	1	0
–	–	–	–	–	–	–	–

The End of Interrupt Command Register is used by the interrupt routine to indicate that the interrupt treatment is complete. Any value can be written because it is only necessary to make a write to this register location to signal the end of interrupt treatment.

## AIC Spurious Vector Register

**Register Name:** AIC\_SPU

**Access Type:** Read/Write

**Reset Value:** 0

**Offset:** 0x134

31	30	29	28	27	26	25	24
SPUVEC							
23	22	21	20	19	18	17	16
SPUVEC							
15	14	13	12	11	10	9	8
SPUVEC							
7	6	5	4	3	2	1	0
SPUVEC							

- SPUVEC: Spurious Interrupt Vector Handler Address**

The user may store the address of the spurious interrupt handler in this register.

## Standard Interrupt Sequence

It is assumed that:

- The Advanced Interrupt Controller has been programmed, AIC\_SVR are loaded with corresponding interrupt service routine addresses and interrupts are enabled.
- The Instruction at address 0x18 (IRQ exception vector address) is  

```
ldr pc, [pc, # - &F20]
```

When NIRQ is asserted, if the bit I of CPSR is 0, the sequence is:

1. The CPSR is stored in SPSR\_irq, the current value of the Program Counter is loaded in the IRQ link register (r14\_irq) and the Program Counter (r15) is loaded with 0x18. In the following cycle during fetch at address 0x1C, the ARM core adjusts r14\_irq, decrementing it by 4.
2. The ARM core enters IRQ Mode, if it is not already.
3. When the instruction loaded at address 0x18 is executed, the Program Counter is loaded with the value read in AIC\_IVR. Reading the AIC\_IVR has the following effects:
  - Set the current interrupt to be the pending one with the highest priority. The current level is the priority level of the current interrupt.
  - De-assert the NIRQ line on the processor. (Even if vectoring is not used, AIC\_IVR must be read in order to de-assert NIRQ)
  - Automatically clear the interrupt, if it has been programmed to be edge triggered
  - Push the current level on to the stack
  - Return the value written in the AIC\_SVR corresponding to the current interrupt
4. The previous step has effect to branch to the corresponding interrupt service routine. This should start by saving the Link Register (r14\_irq) and the SPSR (SPSR\_irq). Note that the Link Register must be decremented by 4 when it is saved, if it is to be restored directly into the Program Counter at the end of the interrupt.
5. Further interrupts can then be unmasked by clearing the I bit in the CPSR, allowing re-assertion of the NIRQ to be taken into account by the core. This can occur if an interrupt with a higher priority than the current one occurs.
6. The Interrupt Handler can then proceed as required, saving the registers which will be used and restoring them at the end. During this phase, an interrupt of priority higher than the current level will restart the sequence from step 1. Note that if the

interrupt is programmed to be level sensitive, the source of the interrupt must be cleared during this phase.

7. The I bit in the CPSR must be set in order to mask interrupts before exiting, to ensure that the interrupt is completed in an orderly manner.
8. The End Of Interrupt Command Register (AIC\_EOICR) must be written in order to indicate to the AIC that the current interrupt is finished. This causes the current level to be popped from the stack, restoring the previous current level if one exists on the stack. If another interrupt is pending, with lower or equal priority than old current level but with higher priority than the new current level, the NIRQ line is re-asserted, but the interrupt sequence does not immediately start because the I bit is set in the core.
9. The SPSR (SPSR\_irq) is restored. Finally, the saved value of the Link Register is restored directly into the PC. This has effect of returning from the interrupt to whatever was being executed before, and of loading the CPSR with the stored SPSR, masking or unmasking the interrupts depending on the state saved in the SPSR (the previous state of the ARM core).

**Note:** The I bit in the SPSR is significant. If it is set, it indicates that the ARM core was just about to mask IRQ interrupts when the mask instruction was interrupted. Hence, when the SPSR is restored, the mask instruction is completed (IRQ is masked).

## Fast Interrupt Sequence

It is assumed that:

- The Advanced Interrupt Controller has been programmed, AIC\_SVR[0] is loaded with fast interrupt service routine address and the fast interrupt is enabled.
- The Instruction at address 0x1C(FIQ exception vector address) is:
- `ldr pc, [pc, # - &F20]`.
- Nested Fast Interrupts are not needed by the user.

When NFIQ is asserted, if the bit F of CPSR is 0, the sequence is:

1. The CPSR is stored in SPSR\_fiq, the current value of the Program Counter is loaded in the FIQ link register (r14\_fiq) and the Program Counter (r15) is loaded with 0x1C. In the following cycle, during fetch at address 0x20, the ARM core adjusts r14\_fiq, decrementing it by 4.
2. The ARM core enters FIQ Mode.
3. When the instruction loaded at address 0x1C is executed, the Program Counter is loaded with the value read in AIC\_FVR. Reading the AIC\_FVR has effect of automatically clearing the fast interrupt (source 0 connected to the FIQ line), if it has been programmed to be edge triggered. In this case only, it de-asserts the NFIQ line on the processor.
4. The previous step has effect to branch to the corresponding interrupt service routine. It is not necessary to save the Link Register(r14\_fiq) and the SPSR(SPSR\_fiq) if nested fast interrupts are not needed.
5. The Interrupt Handler can then proceed as required. It is not necessary to save registers r8 to r13 because FIQ Mode has its own dedicated registers and the user r8 to r13 are banked. The other registers, r0 to r7, must be saved before being used, and restored at the end (before the next step). Note that if the fast interrupt is programmed to be level sensitive, the source of the interrupt must be cleared during this phase in order to de-assert the NFIQ line.
6. Finally, the Link Register (r14\_fiq) is restored into the PC after decrementing it by 4 (with instruction `sub pc, lr, #4` for example). This has effect of returning from the interrupt to whatever was being executed before, and of loading the CPSR with the SPSR, masking or unmasking the fast interrupt depending on the state saved in the SPSR.

**Note:** The F bit in the SPSR is significant. If it is set, it indicates that the ARM core was just about to mask FIQ interrupts when the mask instruction was interrupted. Hence when the SPSR is restored, the interrupted instruction is completed (FIQ is masked).

## **PIO: Parallel I/O Controller**

The AT91X40 Series has 32 programmable I/O lines. Six pins are dedicated as general purpose I/O pins (P16, P17, P18, P19, P23 and P24). Other I/O lines are multiplexed with an external signal of a peripheral to optimize the use of available package pins (see Table 10). The PIO controller also provides an internal interrupt signal to the Advanced Interrupt Controller.

### **Multiplexed I/O Lines**

Some I/O lines are multiplexed with an I/O signal of a peripheral. After reset, the pin is generally controlled by the PIO Controller and is in Input Mode. Table 10 indicates which of these pins are not controlled by the PIO Controller after reset.

When a peripheral signal is not used in an application, the corresponding pin can be used as a parallel I/O. Each parallel I/O line is bi-directional, whether the peripheral defines the signal as input or output. Figure 34 shows the multiplexing of the peripheral signals with Parallel I/O signals.

If a pin is multiplexed between the PIO Controller and a peripheral, the pin is controlled by the registers PIO\_PER (PIO Enable) and PIO\_PDR (PIO Disable). The register PIO\_PSR (PIO Status) indicates whether the pin is controlled by the corresponding peripheral or by the PIO Controller.

If a pin is a general-purpose parallel I/O pin (not multiplexed with a peripheral), PIO\_PER and PIO\_PDR have no effect and PIO\_PSR returns 1 for the bits corresponding to these pins.

When the PIO is selected, the peripheral input line is connected to zero.

### **Output Selection**

The user can enable each individual I/O signal as an output with the registers PIO\_OER (Output Enable) and PIO\_ODR (Output Disable). The output status of the I/O signals can be read in the register PIO\_OSR (Output Status). The direction defined has effect only if the pin is configured to be controlled by the PIO Controller.

### **I/O Levels**

Each pin can be configured to be driven high or low. The level is defined in four different ways, according to the following conditions.

If a pin is controlled by the PIO Controller and is defined as an output (see “Output Selection” above), the level is programmed using the registers PIO\_SODR (Set Output Data) and PIO\_CODR (Clear Output Data). In this case, the programmed value can be read in PIO\_ODSR (Output Data Status).

If a pin is controlled by the PIO Controller and is not defined as an output, the level is determined by the external circuit.

If a pin is not controlled by the PIO Controller, the state of the pin is defined by the peripheral (see peripheral datasheets).

In all cases, the level on the pin can be read in the register PIO\_PDSR (Pin Data Status).

### **Filters**

Optional input glitch filtering is available on each pin and is controlled by the registers PIO\_IFER (Input Filter Enable) and PIO\_IFDR (Input Filter Disable). The input glitch filtering can be selected whether the pin is used for its peripheral function or as a parallel I/O line. The register PIO\_IFSR (Input Filter Status) indicates whether or not the filter is activated for each pin.

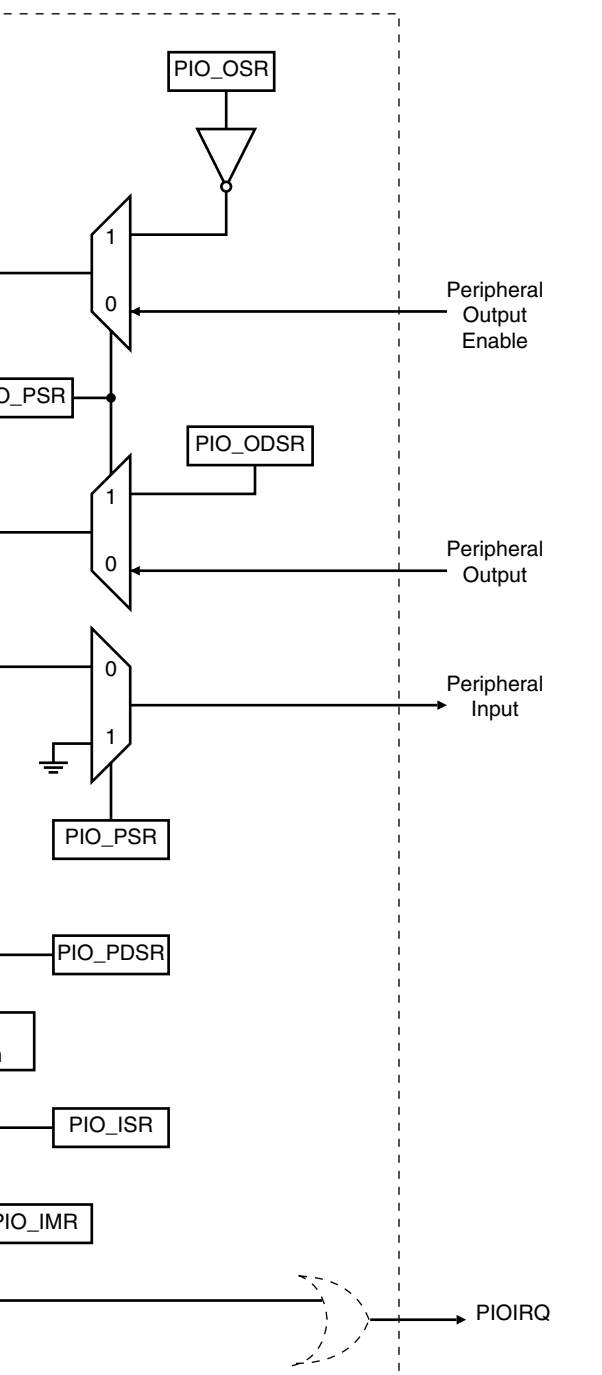

### **Interrupts**

Each parallel I/O can be programmed to generate an interrupt when a level change occurs. This is controlled by the PIO\_IER (Interrupt Enable) and PIO\_IDR (Interrupt Disable) registers which enable/disable the I/O interrupt by setting/clearing the corresponding bit in the PIO\_IMR. When a change in level occurs, the corresponding bit in the PIO\_ISR (Interrupt Status) is set whether the pin is used as a PIO or a peripheral and whether it is defined as input or output. If the corresponding interrupt in PIO\_IMR (Interrupt Mask) is enabled, the PIO interrupt is asserted.

When PIO\_ISR is read, the register is automatically cleared.

### **User Interface**

Each individual I/O is associated with a bit position in the Parallel I/O user interface registers. Each of these registers are 32 bits wide. If a parallel I/O line is not defined, writing to the corresponding bits has no effect. Undefined bits read zero.

**Table 10.** Multiplexed Parallel I/Os

PIO Controller		Peripheral			Reset State	Pin Number
Bit Number <sup>(1)</sup>	Port Name	Port Name	Signal Description	Signal Direction		
0	P0	TCLK0	Timer 0 Clock signal	input	PIO Input	49
1	P1	TIOA0	Timer 0 Signal A	bi-directional	PIO Input	50
2	P2	TIOB0	Timer 0 Signal B	bi-directional	PIO Input	51
3	P3	TCLK1	Timer 1 Clock signal	input	PIO Input	54

0x24	Input Filter Disable Register	PIO_IFDR	Write only	–
0x28	Input Filter Status Register	PIO_IFSR	Read only	0
0x2C	Reserved	–	–	–
0x30	Set Output Data Register	PIO_SODR	Write only	–
0x34	Clear Output Data Register	PIO_CODR	Write only	–
0x38	Output Data Status Register	PIO_ODSR	Read only	0
0x3C	Pin Data Status Register	PIO_PDSR	Read only	(see Note 1)
0x40	Interrupt Enable Register	PIO_IER	Write only	–
0x44	Interrupt Disable Register	PIO_IDR	Write only	–
0x48	Interrupt Mask Register	PIO_IMR	Read only	0
0x4C	Interrupt Status Register	PIO_ISR	Read only	(see Note 2)

- Notes:
1. The reset value of this register depends on the level of the external pins at reset.
  2. This register is cleared at reset. However, the first read of the register can give a value not equal to zero if any changes have occurred on any pins between the reset and the read.

## PIO Enable Register

**Register Name:** PIO\_PER  
**Access Type:** Write only  
**Offset:** 0x00

31	30	29	28	27	26	25	24
P31	P30	P29	P28	P27	P26	P25	P24
23	22	21	20	19	18	17	16
P23	P22	P21	P20	P19	P18	P17	P16
15	14	13	12	11	10	9	8
P15	P14	P13	P12	P11	P10	P9	P8
7	6	5	4	3	2	1	0
P7	P6	P5	P4	P3	P2	P1	P0

This register is used to enable individual pins to be controlled by the PIO Controller instead of the associated peripheral. When the PIO is enabled, the associated peripheral input (if any) is held at logic zero.

- 1 = Enables the PIO to control the corresponding pin (disables peripheral control of the pin).
- 0 = No effect.

## PIO Disable Register

**Register Name:** PIO\_PDR  
**Access Type:** Write Only  
**Offset:** 0x04

31	30	29	28	27	26	25	24
P31	P30	P29	P28	P27	P26	P25	P24
23	22	21	20	19	18	17	16
P23	P22	P21	P20	P19	P18	P17	P16
15	14	13	12	11	10	9	8
P15	P14	P13	P12	P11	P10	P9	P8
7	6	5	4	3	2	1	0
P7	P6	P5	P4	P3	P2	P1	P0

This register is used to disable PIO control of individual pins. When the PIO control is disabled, the normal peripheral function is enabled on the corresponding pin.

- 1 = Disables PIO control (enables peripheral control) on the corresponding pin.
- 0 = No effect.

## PIO Status Register

**Register Name:** PIO\_PSR  
**Access Type:** Read only  
**Reset Value:** 0x01FFFFFF  
**Offset:** 0x08

31	30	29	28	27	26	25	24
P31	P30	P29	P28	P27	P26	P25	P24
23	22	21	20	19	18	17	16
P23	P22	P21	P20	P19	P18	P17	P16
15	14	13	12	11	10	9	8
P15	P14	P13	P12	P11	P10	P9	P8
7	6	5	4	3	2	1	0
P7	P6	P5	P4	P3	P2	P1	P0

This register indicates which pins are enabled for PIO control. This register is updated when PIO lines are enabled or disabled.

- 1 = PIO is active on the corresponding line (peripheral is inactive).
- 0 = PIO is inactive on the corresponding line (peripheral is active).

## PIO Output Enable Register

**Register Name:** PIO\_OER  
**Access Type:** Write only  
**Offset:** 0x10

31	30	29	28	27	26	25	24
P31	P30	P29	P28	P27	P26	P25	P24
23	22	21	20	19	18	17	16
P23	P22	P21	P20	P19	P18	P17	P16
15	14	13	12	11	10	9	8
P15	P14	P13	P12	P11	P10	P9	P8
7	6	5	4	3	2	1	0
P7	P6	P5	P4	P3	P2	P1	P0

This register is used to enable PIO output drivers. If the pin is driven by a peripheral, this has no effect on the pin, but the information is stored. The register is programmed as follows:

- 1 = Enables the PIO output on the corresponding pin.
- 0 = No effect.

## PIO Output Disable Register

**Register Name:** PIO\_ODR  
**Access Type:** Write only  
**Offset:** 0x14

31	30	29	28	27	26	25	24
P31	P30	P29	P28	P27	P26	P25	P24
23	22	21	20	19	18	17	16
P23	P22	P21	P20	P19	P18	P17	P16
15	14	13	12	11	10	9	8
P15	P14	P13	P12	P11	P10	P9	P8
7	6	5	4	3	2	1	0
P7	P6	P5	P4	P3	P2	P1	P0

This register is used to disable PIO output drivers. If the pin is driven by the peripheral, this has no effect on the pin, but the information is stored. The register is programmed as follows:

- 1 = Disables the PIO output on the corresponding pin.
- 0 = No effect.

## PIO Output Status Register

**Register Name:** PIO\_OSR

**Access Type:** Read only

**Reset Value:** 0

**Offset:** 0x18

31	30	29	28	27	26	25	24
P31	P30	P29	P28	P27	P26	P25	P24
23	22	21	20	19	18	17	16
P23	P22	P21	P20	P19	P18	P17	P16
15	14	13	12	11	10	9	8
P15	P14	P13	P12	P11	P10	P9	P8
7	6	5	4	3	2	1	0
P7	P6	P5	P4	P3	P2	P1	P0

This register shows the PIO pin control (output enable) status which is programmed in PIO\_OER and PIO ODR. The defined value is effective only if the pin is controlled by the PIO. The register reads as follows:

1 = The corresponding PIO is output on this line.

0 = The corresponding PIO is input on this line.

## PIO Input Filter Enable Register

**Register Name:** PIO\_IFER

**Access Type:** Write only

**Offset:** 0x20

31	30	29	28	27	26	25	24
P31	P30	P29	P28	P27	P26	P25	P24
23	22	21	20	19	18	17	16
P23	P22	P21	P20	P19	P18	P17	P16
15	14	13	12	11	10	9	8
P15	P14	P13	P12	P11	P10	P9	P8
7	6	5	4	3	2	1	0
P7	P6	P5	P4	P3	P2	P1	P0

This register is used to enable input glitch filters. It affects the pin whether or not the PIO is enabled. The register is programmed as follows:

- 1 = Enables the glitch filter on the corresponding pin.
- 0 = No effect.

## PIO Input Filter Disable Register

**Register Name:** IO\_IFDR

**Access Type:** Write only

**Offset:** 0x24

31	30	29	28	27	26	25	24
P31	P30	P29	P28	P27	P26	P25	P24
23	22	21	20	19	18	17	16
P23	P22	P21	P20	P19	P18	P17	P16
15	14	13	12	11	10	9	8
P15	P14	P13	P12	P11	P10	P9	P8
7	6	5	4	3	2	1	0
P7	P6	P5	P4	P3	P2	P1	P0

This register is used to disable input glitch filters. It affects the pin whether or not the PIO is enabled. The register is programmed as follows:

- 1 = Disables the glitch filter on the corresponding pin.
- 0 = No effect.

## PIO Input Filter Status Register

**Register Name:** PIO\_IFSR

**Access Type:** Read only

**Reset Value:** 0

**Offset:** 0x28

31	30	29	28	27	26	25	24
P31	P30	P29	P28	P27	P26	P25	P24
23	22	21	20	19	18	17	16
P23	P22	P21	P20	P19	P18	P17	P16
15	14	13	12	11	10	9	8
P15	P14	P13	P12	P11	P10	P9	P8
7	6	5	4	3	2	1	0
P7	P6	P5	P4	P3	P2	P1	P0

This register indicates which pins have glitch filters selected. It is updated when PIO outputs are enabled or disabled by writing to PIO\_IFER or PIO\_IFDR.

1 = Filter is selected on the corresponding input (peripheral and PIO).

0 = Filter is not selected on the corresponding input.

## PIO Set Output Data Register

**Register Name:** PIO\_SODR  
**Access Type:** Write only  
**Offset:** 0x30

31	30	29	28	27	26	25	24
P31	P30	P29	P28	P27	P26	P25	P24
23	22	21	20	19	18	17	16
P23	P22	P21	P20	P19	P18	P17	P16
15	14	13	12	11	10	9	8
P15	P14	P13	P12	P11	P10	P9	P8
7	6	5	4	3	2	1	0
P7	P6	P5	P4	P3	P2	P1	P0

This register is used to set PIO output data. It affects the pin only if the corresponding PIO output line is enabled and if the pin is controlled by the PIO. Otherwise, the information is stored.

1 = PIO output data on the corresponding pin is set.  
0 = No effect.

## PIO Clear Output Data Register

**Register Name:** PIO\_CODR  
**Access Type:** Write only  
**Offset:** 0x34

31	30	29	28	27	26	25	24
P31	P30	P29	P28	P27	P26	P25	P24
23	22	21	20	19	18	17	16
P23	P22	P21	P20	P19	P18	P17	P16
15	14	13	12	11	10	9	8
P15	P14	P13	P12	P11	P10	P9	P8
7	6	5	4	3	2	1	0
P7	P6	P5	P4	P3	P2	P1	P0

This register is used to clear PIO output data. It affects the pin only if the corresponding PIO output line is enabled and if the pin is controlled by the PIO. Otherwise, the information is stored.

1 = PIO output data on the corresponding pin is cleared.  
0 = No effect.

## PIO Output Data Status Register

**Register Name:** PIO\_ODSR  
**Access Type:** Read only  
**Reset Value:** 0  
**Offset:** 0x38

31	30	29	28	27	26	25	24
P31	P30	P29	P28	P27	P26	P25	P24
23	22	21	20	19	18	17	16
P23	P22	P21	P20	P19	P18	P17	P16
15	14	13	12	11	10	9	8
P15	P14	P13	P12	P11	P10	P9	P8
7	6	5	4	3	2	1	0
P7	P6	P5	P4	P3	P2	P1	P0

This register shows the output data status which is programmed in PIO\_SODR or PIO\_CODR. The defined value is effective only if the pin is controlled by the PIO Controller and only if the pin is defined as an output.

- 1 = The output data for the corresponding line is programmed to 1.
- 0 = The output data for the corresponding line is programmed to 0.

## PIO Pin Data Status Register

**Register Name:** PIO\_PDSR  
**Access Type:** Read only  
**Reset Value:** see Table 11  
**Offset:** 0x3C

31	30	29	28	27	26	25	24
P31	P30	P29	P28	P27	P26	P25	P24
23	22	21	20	19	18	17	16
P23	P22	P21	P20	P19	P18	P17	P16
15	14	13	12	11	10	9	8
P15	P14	P13	P12	P11	P10	P9	P8
7	6	5	4	3	2	1	0
P7	P6	P5	P4	P3	P2	P1	P0

This register shows the state of the physical pin of the chip. The pin values are always valid regardless of whether the pins are enabled as PIO, peripheral, input or output. The register reads as follows:

- 1 = The corresponding pin is at logic 1.
- 0 = The corresponding pin is at logic 0.

## PIO Interrupt Enable Register

**Register Name:** PIO\_IER  
**Access Type:** Write only  
**Offset:** 0x40

31	30	29	28	27	26	25	24
P31	P30	P29	P28	P27	P26	P25	P24
23	22	21	20	19	18	17	16
P23	P22	P21	P20	P19	P18	P17	P16
15	14	13	12	11	10	9	8
P15	P14	P13	P12	P11	P10	P9	P8
7	6	5	4	3	2	1	0
P7	P6	P5	P4	P3	P2	P1	P0

This register is used to enable PIO interrupts on the corresponding pin. It has effect whether PIO is enabled or not.

- 1 = Enables an interrupt when a change of logic level is detected on the corresponding pin.
- 0 = No effect.

## PIO Interrupt Disable Register

**Register Name:** PIO\_IDR  
**Access Type:** Write only  
**Offset:** 0x44

31	30	29	28	27	26	25	24
P31	P30	P29	P28	P27	P26	P25	P24
23	22	21	20	19	18	17	16
P23	P22	P21	P20	P19	P18	P17	P16
15	14	13	12	11	10	9	8
P15	P14	P13	P12	P11	P10	P9	P8
7	6	5	4	3	2	1	0
P7	P6	P5	P4	P3	P2	P1	P0

This register is used to disable PIO interrupts on the corresponding pin. It has effect whether the PIO is enabled or not.

- 1 = Disables the interrupt on the corresponding pin. Logic level changes are still detected.
- 0 = No effect.

## PIO Interrupt Mask Register

**Register Name:** PIO\_IMR  
**Access Type:** Read Only  
**Reset Value:** 0  
**Offset:** 0x48

31	30	29	28	27	26	25	24
P31	P30	P29	P28	P27	P26	P25	P24
23	22	21	20	19	18	17	16
P23	P22	P21	P20	P19	P18	P17	P16
15	14	13	12	11	10	9	8
P15	P14	P13	P12	P11	P10	P9	P8
7	6	5	4	3	2	1	0
P7	P6	P5	P4	P3	P2	P1	P0

This register shows which pins have interrupts enabled. It is updated when interrupts are enabled or disabled by writing to PIO\_IER or PIO\_IDR.

- 1 = Interrupt is enabled on the corresponding input pin.
- 0 = Interrupt is not enabled on the corresponding input pin.

## PIO Interrupt Status Register

**Register Name:** PIO\_ISR  
**Access Type:** Read only  
**Reset Value:** 0  
**Offset:** 0x4C

31	30	29	28	27	26	25	24
P31	P30	P29	P28	P27	P26	P25	P24
23	22	21	20	19	18	17	16
P23	P22	P21	P20	P19	P18	P17	P16
15	14	13	12	11	10	9	8
P15	P14	P13	P12	P11	P10	P9	P8
7	6	5	4	3	2	1	0
P7	P6	P5	P4	P3	P2	P1	P0

This register indicates for each pin when a logic value change has been detected (rising or falling edge). This is valid whether the PIO is selected for the pin or not and whether the pin is an input or output.

The register is reset to zero following a read, and at reset.

- 1 = At least one change has been detected on the corresponding pin since the register was last read.
- 0 = No change has been detected on the corresponding pin since the register was last read.

## WD: Watchdog Timer

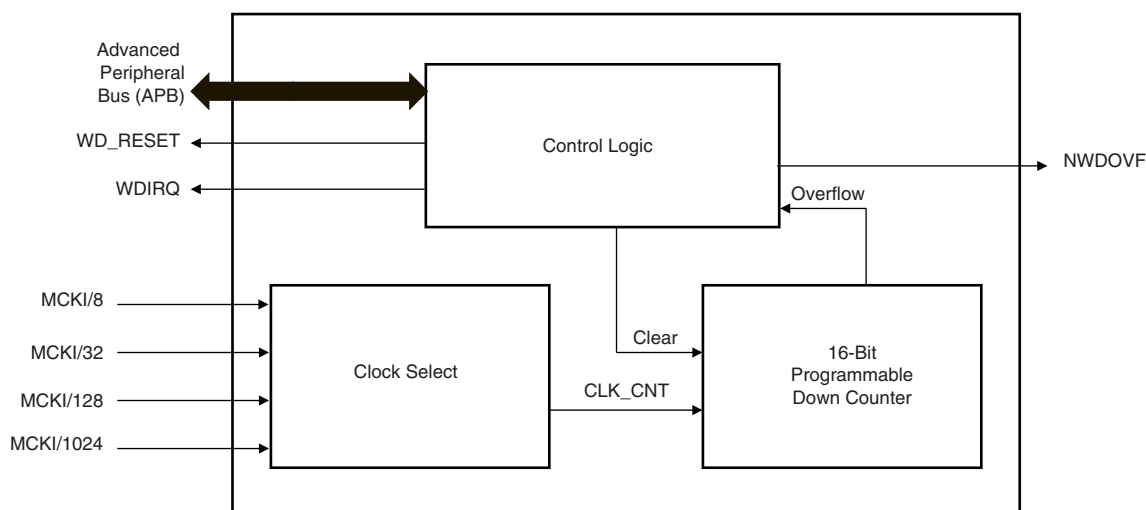

The AT91X40 Series has an internal watchdog timer which can be used to prevent system lock-up if the software becomes trapped in a deadlock. In normal operation the user reloads the watchdog at regular intervals before the timer overflow occurs. If an overflow does occur, the watchdog timer generates one or a combination of the following signals, depending on the parameters in WD\_OMR (Overflow Mode Register):

- If RSTEN is set, an internal reset is generated (WD\_RESET as shown in Figure 35).
- If IRQEN is set, a pulse is generated on the signal WDIRQ which is connected to the Advanced Interrupt Controller
- If EXTEN is set, a low level is driven on the NWDOVF signal for a duration of 8 MCK cycles.

The watchdog timer has a 16-bit down counter. Bits 12-15 of the value loaded when the watchdog is restarted are programmable using the HPVC parameter in WD\_CMR (Clock Mode). Four clock sources are available to the watchdog counter: MCK/8, MCK/32, MCK/128 or MCK/1024. The selection is made using the WDCLKS parameter in WD\_CMR. This provides a programmable time-out period of 1 ms to 2 sec. with a 33 MHz system clock.

All write accesses are protected by control access keys to help prevent corruption of the watchdog should an error condition occur. To update the contents of the mode and control registers it is necessary to write the correct bit pattern to the control access key bits at the same time as the control bits are written (the same write access).

**Figure 35.** Watchdog Timer Block Diagram

## WD User Interface

**WD Base Address:** 0xFFFF8000

**Table 12.** WD Memory Map

Offset	Register	Name	Access	Reset State
0x00	Overflow Mode Register	WD_OMR	Read/Write	0
0x04	Clock Mode Register	WD_CMR	Read/Write	0
0x08	Control Register	WD_CR	Write only	–
0x0C	Status Register	WD_SR	Read only	0

## WD Overflow Mode Register

**Name:** WD\_OMR  
**Access:** Read/Write  
**Reset Value:** 0  
**Offset:** 0x00

0xC071 = Watch Dog counter is restarted.  
Other value = No effect.

## WD Status Register

**Name:** WD\_SR  
**Access:** Read only  
**Reset Value:** 0  
**Offset:** 0x0C

31	30	29	28	27	26	25	24
—	—	—	—	—	—	—	—
23	22	21	20	19	18	17	16
—	—	—	—	—	—	—	—
15	14	13	12	11	10	9	8
—	—	—	—	—	—	—	—
7	6	5	4	3	2	1	0
—	—	—	—	—	—	—	WDOVF

- **WDOVF: Watchdog Overflow**  
0 = No watchdog overflow.  
1 = A watchdog overflow has occurred since the last restart of the watchdog counter or since internal or external reset.

## **WD Enabling Sequence**

To enable the Watchdog Timer the sequence is as follows:

1. Disable the Watchdog by clearing the bit WDEN:  
Write 0x2340 to WD\_OMR  
This step is unnecessary if the WD is already disabled (reset state).
2. Initialize the WD Clock Mode Register:  
Write 0x373C to WD\_CMR  
(HPCV = 15 and WDCLKS = MCK/8)
3. Restart the timer:  
Write 0xC071 to WD\_CR
4. Enable the watchdog:  
Write 0x2345 to WD\_OMR (interrupt enabled)

## SF: Special Function Registers

The AT91X40 Series provides registers which implement the following special functions.

- Chip identification
- RESET status
- Protect Mode (see Protect Mode on page 48)

### Chip Identification

Table 13 provides the Chip ID values for the products described in this datasheet.

**Table 13.** Chip ID Values

Product	Chip
AT91M40800	0x14080044
AT91R40807	0x44080746
AT91M40807	0x014080745

### SF User Interface

**Chip ID Base Address** = 0xFFFF0000

**Table 14.** SF Memory Map

Offset	Register	Name	Access	Reset State
0x00	Chip ID Register	SF_CIDR	Read only	Hardwired
0x04	Chip ID Extension Register	SF_EXID	Read only	Hardwired
0x08	Reset Status Register	SF_RSR	Read only	See register description

–	–	AIC	–	–	–	–	–

- PMRKEY: Protect Mode Register Key**

Used only when writing SF\_PMR. PMRKEY is reads 0.

0x27A8: Write access in SF\_PMR is allowed.

Other value: Write access in SF\_PMR is prohibited.

- AIC: AIC Protect Mode Enable**

0 = The Advanced Interrupt Controller runs in Normal Mode.

1 = The Advanced Interrupt Controller runs in Protect Mode.

See Protect Mode on page 48.

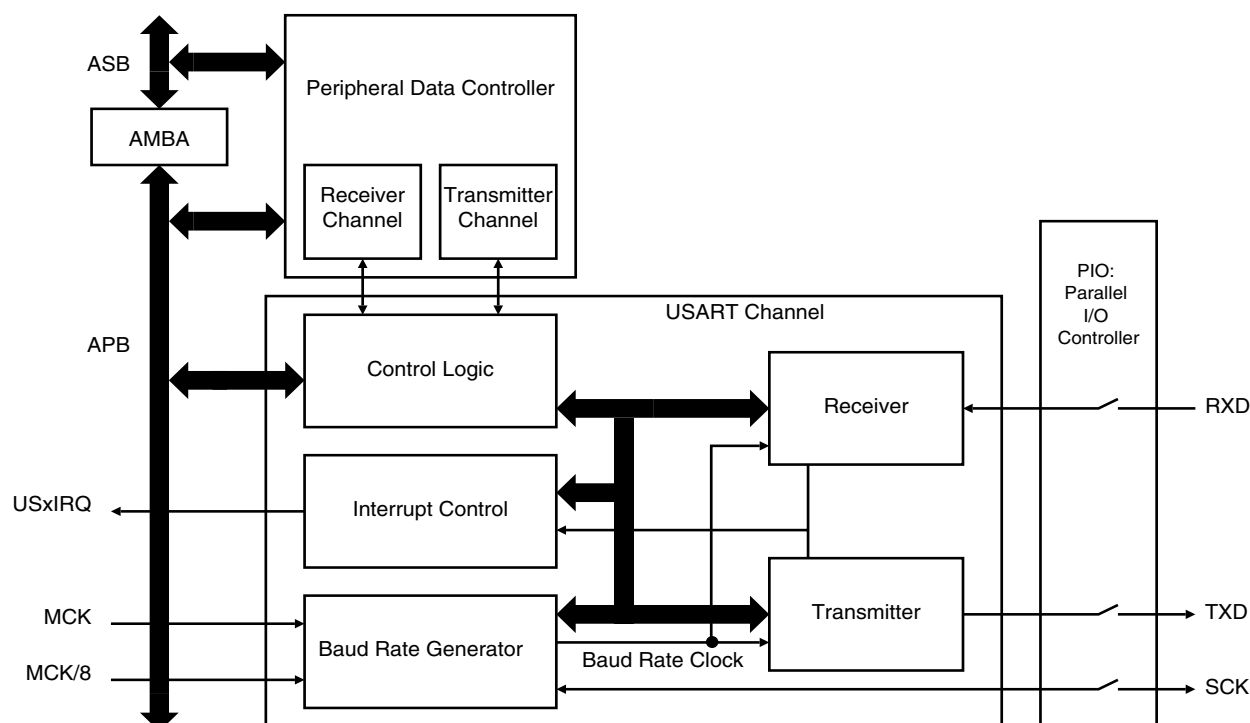

## USART: Universal Synchronous/Asynchronous Receiver/Transmitter

The AT91X40 Series provides two identical, full-duplex, universal synchronous/asynchronous receiver/transmitters that interface to the APB and are connected to the Peripheral Data Controller.

The main features are:

- Programmable Baud Rate Generator
- Parity, Framing and Overrun Error Detection
- Line Break Generation and Detection
- Automatic Echo, Local Loopback and Remote Loopback channel modes
- Multi-drop Mode: Address Detection and Generation
- Interrupt Generation
- Two Dedicated Peripheral Data Controller channels
- 5-, 6-, 7-, 8- and 9-bit character length

**Figure 36.** USART Block Diagram

## Pin Description

Each USART channel has the following external signals:

Name	Description
SCK	USART Serial clock can be configured as input or output: SCK is configured as input if an External clock is selected (USCLKS[1] = 1) SCK is driven as output if the External Clock is disabled (USCLKS[1] = 0) and Clock output is enabled (CLKO = 1)
TXD	Transmit Serial Data is an output
RXD	Receive Serial Data is an input

- Notes:
1. After a hardware reset, the USART pins are not enabled by default (see PIO: Parallel I/O Controller on page 61). The user must configure the PIO Controller before enabling the transmitter or receiver.
  2. If the user selects one of the internal clocks, SCK can be configured as a PIO.

## Baud Rate Generator

The Baud Rate Generator provides the bit period clock (the Baud Rate clock) to both the Receiver and the Transmitter.

The Baud Rate Generator can select between external and internal clock sources. The external clock source is SCK. The internal clock sources can be either the master clock (MCK) or the master clock divided by 8 (MCK/8).

**Note:** In all cases, if an external clock is used, the duration of each of its levels must be longer than the system clock (MCK) period. The external clock frequency must be at least 2.5 times lower than the system clock.

When the USART is programmed to operate in Asynchronous Mode (SYNC = 0 in the Mode Register US\_MR), the selected clock is divided by 16 times the value (CD) written in US\_BRGR (Baud Rate Generator Register). If US\_BRGR is set to 0, the Baud Rate Clock is disabled.

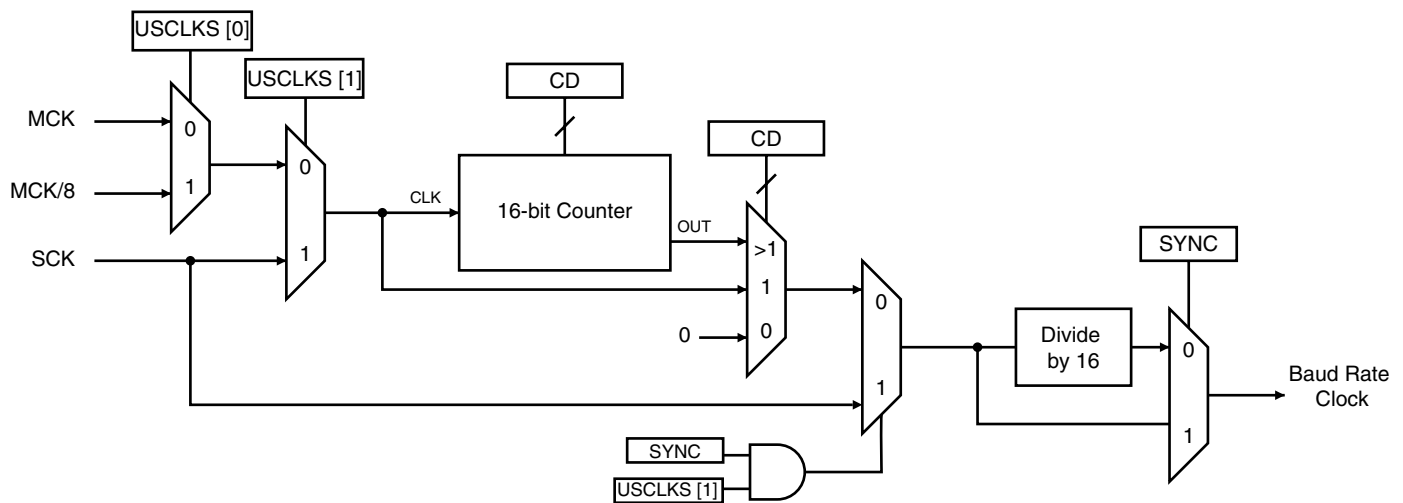

$$\text{Baud Rate} = \frac{\text{Selected Clock}}{16 \times \text{CD}}$$

When the USART is programmed to operate in Synchronous Mode (SYNC = 1) and the selected clock is internal (USCLKS[1] = 0 in the Mode Register US\_MR), the Baud Rate Clock is the internal selected clock divided by the value written in US\_BRGR. If US\_BRGR is set to 0, the Baud Rate Clock is disabled.

$$\text{Baud Rate} = \frac{\text{Selected Clock}}{\text{CD}}$$

In Synchronous Mode with external clock selected (USCLKS[1] = 1), the clock is provided directly by the signal on the SCK pin. No division is active. The value written in US\_BRGR has no effect.

**Figure 37.** Baud Rate Generator

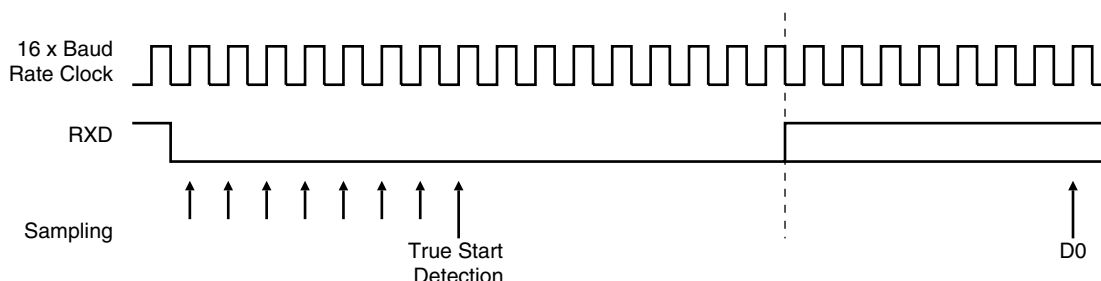

## Receiver

### Asynchronous Receiver

The USART is configured for asynchronous operation when SYNC = 0 (bit 7 of US\_MR). In Asynchronous Mode, the USART detects the start of a received character by sampling the RXD signal until it detects a valid start bit. A low level (space) on RXD is interpreted as a valid start bit if it is detected for more than 7 cycles of the sampling clock, which is 16 times the baud rate. Hence a space which is longer than 7/16 of the bit period is detected as a valid start bit. A space which is 7/16 of a bit period or shorter is ignored and the receiver continues to wait for a valid start bit.

When a valid start bit has been detected, the receiver samples the RXD at the theoretical mid-point of each bit. It is assumed that each bit lasts 16 cycles of the sampling clock (one bit period) so the sampling point is 8 cycles (0.5 bit periods) after the start of the bit. The first sampling point is therefore 24 cycles (1.5 bit periods) after the falling edge of the start bit was detected. Each subsequent bit is sampled 16 cycles (1 bit period) after the previous one.

**Figure 38.** Asynchronous Mode: Start Bit Detection

**Figure 39.** Asynchronous Mode: Character Reception

Example: 8-bit, parity enabled 1 stop

## Synchronous Receiver

When configured for synchronous operation (SYNC = 1), the receiver samples the RXD signal on each rising edge of the Baud Rate clock. If a low level is detected, it is consid-

ered as a start. Data bits, parity bit and stop bit are sampled and the receiver waits for the next start bit. See example in Figure 40.

**Figure 40.** Synchronous Mode: Character Reception

### Receiver Ready

When a complete character is received, it is transferred to the US\_RHR and the RXRDY status bit in US\_CSR is set. If US\_RHR has not been read since the last transfer, the OVRE status bit in US\_CSR is set.

### Parity Error

Each time a character is received, the receiver calculates the parity of the received data bits, in accordance with the field PAR in US\_MR. It then compares the result with the received parity bit. If different, the parity error bit PARE in US\_CSR is set.

### Framing Error

If a character is received with a stop bit at low level and with at least one data bit at high level, a framing error is generated. This sets FRAME in US\_CSR.

### Time-out

This function allows an idle condition on the RXD line to be detected. The maximum delay for which the USART should wait for a new character to arrive while the RXD line is inactive (high level) is programmed in US\_RTOR (Receiver Time-out). When this register is set to 0, no time-out is detected. Otherwise, the receiver waits for a first character and then initializes a counter which is decremented at each bit period and reloaded at each byte reception. When the counter reaches 0, the TIMEOUT bit in US\_CSR is set. The user can restart the wait for a first character with the STTTO (Start Time-out) bit in US\_CR.

Calculation of time-out duration:

$$\text{Duration} = \text{Value} \times 4 \times \text{Bit period}$$

## Transmitter

The transmitter has the same behavior in both synchronous and asynchronous operating modes. Start bit, data bits, parity bit and stop bits are serially shifted, lowest significant bit first, on the falling edge of the serial clock. See example in Figure 41.

The number of data bits is selected in the CHRL field in US\_MR.

The parity bit is set according to the PAR field in US\_MR.

The number of stop bits is selected in the NBSTOP field in US\_MR.

When a character is written to US\_THR (Transmit Holding), it is transferred to the Shift Register as soon as it is empty. When the transfer occurs, the TXRDY bit in US\_CSR is set until a new character is written to US\_THR. If Transmit Shift Register and US\_THR are both empty, the TXEMPTY bit in US\_CSR is set.

## Time-guard

The Time-guard function allows the transmitter to insert an idle state on the TXD line between two characters. The duration of the idle state is programmed in US\_TTGR

(Transmitter Time-guard). When this register is set to zero, no time-guard is generated. Otherwise, the transmitter holds a high level on TXD after each transmitted byte during the number of bit periods programmed in US\_TTGR

$$\text{Idle state duration between two characters} = \frac{\text{Time-guard Value}}{\text{Bit Period}} \times \text{Bit Period}$$

## Multi-drop Mode

When the field PAR in US\_MR equals 11X (binary value), the USART is configured to run in Multi-drop Mode. In this case, the parity error bit PARE in US\_CSR is set when data is detected with a parity bit set to identify an address byte. PARE is cleared with the Reset Status Bits Command (RSTSTA) in US\_CR. If the parity bit is detected low, identifying a data byte, PARE is not set.

The transmitter sends an address byte (parity bit set) when a Send Address Command (SEND A) is written to US\_CR. In this case, the next byte written to US\_THR will be transmitted as an address. After this any byte transmitted will have the parity bit cleared.

**Figure 41.** Synchronous and Asynchronous Modes: Character Transmission

## Break

A break condition is a low signal level which has a duration of at least one character (including start/stop bits and parity).

### Transmit Break

The transmitter generates a break condition on the TXD line when STTBRK is set in US\_CR (Control Register). In this case, the character present in the Transmit Shift Register is completed before the line is held low.

To cancel a break condition on the TXD line, the STPBRK command in US\_CR must be set. The USART completes a minimum break duration of one character length. The TXD line then returns to high level (idle state) for at least 12 bit periods to ensure that the end of break is correctly detected. Then the transmitter resumes normal operation.

The BREAK is managed like a character:

- The STTBRK and the STPBRK commands are performed only if the transmitter is ready (bit TXRDY = 1 in US\_CSR)
- The STTBRK command blocks the transmitter holding register (bit TXRDY is cleared in US\_CSR) until the break has started
- A break is started when the Shift Register is empty (any previous character is fully transmitted). TXEMPTY is cleared in US\_CSR. The break blocks the transmitter shift register until it is completed (high level for at least 12 bit periods after the STPBRK command is requested)

In order to avoid unpredictable states:

- STTBRK and STPBRK commands must not be requested at the same time
- Once an STTBRK command is requested, further STTBRK commands are ignored until the BREAK is ended (high level for at least 12 bit periods)
- All STPBRK commands requested without a previous STTBRK command are ignored
- A byte written into the Transmit Holding Register while a break is pending but not started (US\_CSR.TXRDY = 0) is ignored
- It is *not permitted* to write new data in the Transmit Holding Register while a break is in progress (STPBRK has not been requested), even though TXRDY = 1 in US\_CSR.
- A new STTBRK command *must not* be issued until an existing break has ended (TXEMPTY = 1 in US\_CSR)

The standard break transmission sequence is:

1. Wait for the transmitter ready (US\_CSR.TXRDY = 1)
2. Send the STTBRK command (write 0x0200 to US\_CR)

3. Wait for the transmitter ready (TXRDY = 1 in US\_CSR)
4. Send the STPBRK command (write 0x0400 to US\_CR)

The next byte can then be sent:

5. Wait for the transmitter ready (TXRDY = 1 in US\_CSR)
6. Send the next byte (write byte to US\_THR)

Each of these steps can be scheduled by using the interrupt if the bit TXRDY in US\_IMR is set.

For character transmission, the USART channel must be enabled before sending a break.

### Receive Break

The receiver detects a break condition when all data, parity and stop bits are low. When the low stop bit is detected, the receiver asserts the RXBRK bit in US\_CSR. An end of receive break is detected by a high level for at least 2/16 of a bit period in Asynchronous Mode or at least one sample in Synchronous Mode. RXBRK is also asserted when an end of break is detected.

Both the beginning and the end of a break can be detected by interrupt if the bit US\_IMR.RXBRK is set.

### Peripheral Data Controller

Each USART channel is closely connected to a corresponding Peripheral Data Controller channel. One is dedicated to the receiver. The other is dedicated to the transmitter.

Note: The PDC is disabled if 9-bit character length is selected (MODE9 = 1) in US\_MR.

The PDC channel is programmed using US\_TPR (Transmit Pointer) and US\_TCR (Transmit Counter) for the transmitter and US\_RPR (Receive Pointer) and US\_RCR (Receive Counter) for the receiver. The status of the PDC is given in US\_CSR by the ENDTX bit for the transmitter and by the ENDRX bit for the receiver.

The pointer registers (US\_TPR and US\_RPR) are used to store the address of the transmit or receive buffers. The counter registers (US\_TCR and US\_RCR) are used to store the size of these buffers.

The receiver data transfer is triggered by the RXRDY bit and the transmitter data transfer is triggered by TXRDY. When a transfer is performed, the counter is decremented and the pointer is incremented. When the counter reaches 0, the status bit is set (ENDRX for the receiver, ENDTX for the transmitter in US\_CSR) which can be programmed to

generate an interrupt. Transfers are then disabled until a new non-zero counter value is programmed.

## Interrupt Generation

Each status bit in US\_CSR has a corresponding bit in US\_IER (Interrupt Enable) and US\_IDR (Interrupt Disable) which controls the generation of interrupts by asserting the USART interrupt line connected to the Advanced Interrupt Controller. US\_IMR (Interrupt Mask Register) indicates the status of the corresponding bits.

When a bit is set in US\_CSR and the same bit is set in US\_IMR, the interrupt line is asserted.

## Channel Modes

The USART can be programmed to operate in three different test modes, using the field CHMODE in US\_MR.

Automatic Echo Mode allows bit by bit re-transmission. When a bit is received on the RXD line, it is sent to the TXD line. Programming the transmitter has no effect.

Local Loopback Mode allows the transmitted characters to be received. TXD and RXD pins are not used and the output of the transmitter is internally connected to the input of the receiver. The RXD pin level has no effect and the TXD pin is held high, as in idle state.

Remote Loopback Mode directly connects the RXD pin to the TXD pin. The Transmitter and the Receiver are disabled and have no effect. This mode allows bit by bit re-transmission.

**Figure 42. Channel Modes**

### Automatic Echo

### Local Loopback

### Remote Loopback

1	0	Seven Bits
1	1	Eight Bits

Start, stop and parity bits are added to the character length.

- SYNC: Synchronous Mode Select**  
 0 = USART operates in Asynchronous Mode.  
 1 = USART operates in Synchronous Mode.
- PAR: Parity Type**

PAR			Parity Type
0	0	0	Even Parity
0	0	1	Odd Parity
0	1	0	Parity Forced to 0 (Space)
0	1	1	Parity Forced to 1 (Mark)
1	0	x	No Parity
1	1	x	Multi-drop Mode

- **NBSTOP: Number of Stop Bits**

The interpretation of the number of stop bits depends on SYNC.

NBSTOP		Asynchronous (SYNC = 0)	Synchronous (SYNC = 1)
0	0	1 Stop Bit	1 Stop Bit
0	1	1.5 Stop Bits	Reserved
1	0	2 Stop Bits	2 Stop Bits
1	1	Reserved	Reserved

- **CHMODE: Channel Mode**

CHMODE		Mode Description
0	0	Normal Mode The USART Channel operates as an Rx/Tx USART.
0	1	Automatic Echo Receiver Data Input is connected to the TXD pin.
1	0	Local Loopback Transmitter Output Signal is connected to Receiver Input Signal.
1	1	Remote Loopback RXD pin is internally connected to TXD pin.

- **MODE9: 9-bit Character Length**

0 = CHRL defines character length.

1 = 9-bit character length.

- **CKLO: Clock Output Select**

0 = The USART does not drive the SCK pin.

1 = The USART drives the SCK pin if USCLKS[1] is 0.

## USART Interrupt Enable Register

**Name:** US\_IER  
**Access Type:** Write only  
**Offset:** 0x08

31	30	29	28	27	26	25	24
–	–	–	–	–	–	–	–
23	22	21	20	19	18	17	16
–	–	–	–	–	–	–	–
15	14	13	12	11	10	9	8
–	–	–	–	–	–	TXEMPTY	TIMEOUT
7	6	5	4	3	2	1	0
PARE	FRAME	OVRE	ENDTX	ENDRX	RXBRK	TXRDY	RXRDY

- **RXRDY: Enable RXRDY Interrupt**  
0 = No effect.  
1 = Enables RXRDY Interrupt.
- **TXRDY: Enable TXRDY Interrupt**  
0 = No effect.  
1 = Enables TXRDY Interrupt.
- **RXBRK: Enable Receiver Break Interrupt**  
0 = No effect.  
1 = Enables Receiver Break Interrupt.
- **ENDRX: Enable End of Receive Transfer Interrupt**  
0 = No effect.  
1 = Enables End of Receive Transfer Interrupt.
- **ENDTX: Enable End of Transmit Interrupt**  
0 = No effect.  
1 = Enables End of Transmit Interrupt.
- **OVRE: Enable Overrun Error Interrupt**  
0 = No effect.  
1 = Enables Overrun Error Interrupt.
- **FRAME: Enable Framing Error Interrupt**  
0 = No effect.  
1 = Enables Framing Error Interrupt.
- **PARE: Enable Parity Error Interrupt**  
0 = No effect.  
1 = Enables Parity Error Interrupt.
- **TIMEOUT: Enable Time-out Interrupt**  
0 = No effect.  
1 = Enables Reception Time-out Interrupt.
- **TXEMPTY: Enable TXEMPTY Interrupt**  
0 = No effect.  
1 = Enables TXEMPTY Interrupt.

## USART Interrupt Disable Register

**Name:** US\_IDR  
**Access Type:** Write only  
**Offset:** 0x0C

31	30	29	28	27	26	25	24
–	–	–	–	–	–	–	–
23	22	21	20	19	18	17	16
–	–	–	–	–	–	–	–
15	14	13	12	11	10	9	8
–	–	–	–	–	–	TXEMPTY	TIMEOUT
7	6	5	4	3	2	1	0
PARE	FRAME	OVRE	ENDTX	ENDRX	RXBRK	TXRDY	RXRDY

- **RXRDY: Disable RXRDY Interrupt**  
0 = No effect.  
1 = Disables RXRDY Interrupt.
- **TXRDY: Disable TXRDY Interrupt**  
0 = No effect.  
1 = Disables TXRDY Interrupt.
- **RXBRK: Disable Receiver Break Interrupt**  
0 = No effect.  
1 = Disables Receiver Break Interrupt.
- **ENDRX: Disable End of Receive Transfer Interrupt**  
0 = No effect.  
1 = Disables End of Receive Transfer Interrupt.
- **ENDTX: Disable End of Transmit Interrupt**  
0 = No effect.  
1 = Disables End of Transmit Interrupt.
- **OVRE: Disable Overrun Error Interrupt**  
0 = No effect.  
1 = Disables Overrun Error Interrupt.
- **FRAME: Disable Framing Error Interrupt**  
0 = No effect.  
1 = Disables Framing Error Interrupt.
- **PARE: Disable Parity Error Interrupt**  
0 = No effect.  
1 = Disables Parity Error Interrupt.
- **TIMEOUT: Disable Time-out Interrupt**  
0 = No effect.  
1 = Disables Receiver Time-out Interrupt.
- **TXEMPTY: Disable TXEMPTY Interrupt**  
0 = No effect.  
1 = Disables TXEMPTY Interrupt.

## USART Interrupt Mask Register

**Name:** US\_IMR  
**Access Type:** Read only  
**Reset Value:** 0  
**Offset:** 0x10

31	30	29	28	27	26	25	24
–	–	–	–	–	–	–	–
23	22	21	20	19	18	17	16
–	–	–	–	–	–	–	–
15	14	13	12	11	10	9	8
–	–	–	–	–	–	TXEMPTY	TIMEOUT
7	6	5	4	3	2	1	0
PARE	FRAME	OVRE	ENDTX	ENDRX	RXBRK	TXRDY	RXRDY

- RXRDY: Mask RXRDY Interrupt**  
 0 = RXRDY Interrupt is Disabled  
 1 = RXRDY Interrupt is Enabled
- TXRDY: Mask TXRDY Interrupt**  
 0 = TXRDY Interrupt is Disabled  
 1 = TXRDY Interrupt is Enabled
- RXBRK: Mask Receiver Break Interrupt**  
 0 = Receiver Break Interrupt is Disabled  
 1 = Receiver Break Interrupt is Enabled
- ENDRX: Mask End of Receive Transfer Interrupt**  
 0 = End of Receive Transfer Interrupt is Disabled  
 1 = End of Receive Transfer Interrupt is Enabled
- ENDTX: Mask End of Transmit Interrupt**  
 0 = End of Transmit Interrupt is Disabled  
 1 = End of Transmit Interrupt is Enabled
- OVRE: Mask Overrun Error Interrupt**  
 0 = Overrun Error Interrupt is Disabled  
 1 = Overrun Error Interrupt is Enabled
- FRAME: Mask Framing Error Interrupt**  
 0 = Framing Error Interrupt is Disabled  
 1 = Framing Error Interrupt is Enabled
- PARE: Mask Parity Error Interrupt**  
 0 = Parity Error Interrupt is Disabled  
 1 = Parity Error Interrupt is Enabled
- TIMEOUT: Mask Time-out Interrupt**  
 0 = Receive Time-out Interrupt is Disabled  
 1 = Receive Time-out Interrupt is Enabled
- TXEMPTY: Mask TXEMPTY Interrupt**  
 0 = TXEMPTY Interrupt is Disabled.  
 1 = TXEMPTY Interrupt is Enabled.

## USART Channel Status Register

**Name:** US\_CSR  
**Access Type:** Read only  
**Reset Value:** 0x18  
**Offset:** 0x14

31	30	29	28	27	26	25	24
–	–	–	–	–	–	–	–
23	22	21	20	19	18	17	16
–	–	–	–	–	–	–	–
15	14	13	12	11	10	9	8
–	–	–	–	–	–	TXEMPTY	TIMEOUT
7	6	5	4	3	2	1	0
PARE	FRAME	OVRE	ENDTX	ENDRX	RXBRK	TXRDY	RXRDY

- **RXRDY: Receiver Ready**  
 0 = No complete character has been received since the last read of the US\_RHR or the receiver is disabled.  
 1 = At least one complete character has been received and the US\_RHR has not yet been read.
- **TXRDY: Transmitter Ready**  
 0 = US\_THR contains a character waiting to be transferred to the Transmit Shift Register, or an STTBRK command has been requested.  
 1 = US\_THR is empty and there is no Break request pending TSR availability.  
 Equal to zero when the USART is disabled or at reset. Transmitter Enable command (in US\_CR) sets this bit to one.
- **RXBRK: Break Received/End of Break**  
 0 = No Break Received nor End of Break has been detected since the last “Reset Status Bits” command in the Control Register.  
 1 = Break Received or End of Break has been detected since the last “Reset Status Bits” command in the Control Register.
- **ENDRX: End of Receiver Transfer**  
 0 = The End of Transfer signal from the Peripheral Data Controller channel dedicated to the receiver is inactive.  
 1 = The End of Transfer signal from the Peripheral Data Controller channel dedicated to the receiver is active.
- **ENDTX: End of Transmitter Transfer**  
 0 = The End of Transfer signal from the Peripheral Data Controller channel dedicated to the transmitter is inactive.  
 1 = The End of Transfer signal from the Peripheral Data Controller channel dedicated to the transmitter is active.
- **OVRE: Overrun Error**  
 0 = No byte has been transferred from the Receive Shift Register to the US\_RHR when RxRDY was asserted since the last “Reset Status Bits” command.  
 1 = At least one byte has been transferred from the Receive Shift Register to the US\_RHR when RxRDY was asserted since the last “Reset Status Bits” command.
- **FRAME: Framing Error**  
 0 = No stop bit has been detected low since the last “Reset Status Bits” command.  
 1 = At least one stop bit has been detected low since the last “Reset Status Bits” command.
- **PARE: Parity Error**  
 1 = At least one parity bit has been detected false (or a parity bit high in Multi-drop Mode) since the last “Reset Status Bits” command.  
 0 = No parity bit has been detected false (or a parity bit high in Multi-drop Mode) since the last “Reset Status Bits” command.
- **TIMEOUT: Receiver Time-out**  
 0 = There has not been a time-out since the last “Start Time-out” command or the Time-out Register is 0.  
 1 = There has been a time-out since the last “Start Time-out” command.
- **TXEMPTY: Transmitter Empty**  
 0 = There are characters in either US\_THR or the Transmit Shift Register or a Break is being transmitted.  
 1 = There are no characters in US\_THR and the Transmit Shift Register and Break is not active.  
 Equal to zero when the USART is disabled or at reset. Transmitter Enable command (in US\_CR) sets this bit to one.

## USART Receiver Holding Register

**Name:** US\_RHR  
**Access Type:** Read only  
**Reset Value:** 0  
**Offset:** 0x18

31	30	29	28	27	26	25	24
–	–	–	–	–	–	–	–
23	22	21	20	19	18	17	16
–	–	–	–	–	–	–	–
15	14	13	12	11	10	9	8
–	–	–	–	–	–	–	–
7	6	5	4	3	2	1	0
RXCHR							

- RXCHR: Received Character**

Last character received if RXRDY is set. When number of data bits is less than 8 bits, the bits are right-aligned.  
 All non-significant bits read zero.

## USART Transmitter Holding Register

**Name:** US\_THR  
**Access Type:** Write only  
**Offset:** 0x1C

31	30	29	28	27	26	25	24
–	–	–	–	–	–	–	–
23	22	21	20	19	18	17	16
–	–	–	–	–	–	–	–
15	14	13	12	11	10	9	8
–	–	–	–	–	–	–	–
7	6	5	4	3	2	1	0
TXCHR							

- TXCHR: Character to be Transmitted**

Next character to be transmitted after the current character if TXRDY is not set. When number of data bits is less than 8 bits, the bits are right-aligned.

## USART Baud Rate Generator Register

**Name:** US\_BRGR  
**Access Type:** Read/Write  
**Reset Value:** 0  
**Offset:** 0x20

31	30	29	28	27	26	25	24
—	—	—	—	—	—	—	—
23	22	21	20	19	18	17	16
—	—	—	—	—	—	—	—
15	14	13	12	11	10	9	8
CD							
7	6	5	4	3	2	1	0
CD							

- CD: Clock Divisor**

This register has no effect if Synchronous Mode is selected with an external clock.

CD	Effect
0	Disables Clock
1	Clock Divisor Bypass <sup>(1)</sup>
2 to 65535	Baud Rate (Asynchronous Mode) = Selected Clock / (16 x CD) Baud Rate (Synchronous Mode) = Selected Clock / CD <sup>(2)</sup>

Notes: 1. Clock divisor bypass (CD = 1) must not be used when internal clock MCK is selected (USCLKS = 0).  
 2. In Synchronous Mode, the value programmed must be even to ensure a 50:50 mark:space ratio.

## USART Receiver Time-out Register

**Name:** US\_RTOR  
**Access Type:** Read/Write  
**Reset Value:** 0  
**Offset:** 0x24

31	30	29	28	27	26	25	24
–	–	–	–	–	–	–	–
23	22	21	20	19	18	17	16
–	–	–	–	–	–	–	–
15	14	13	12	11	10	9	8
–	–	–	–	–	–	–	–
7	6	5	4	3	2	1	0
TO							

- TO: Time-out Value**

When a value is written to this register, a Start Time-out Command is automatically performed.

TO	
0	Disables the RX Time-out function.
1 - 255	The Time-out counter is loaded with TO when the Start Time-out Command is given or when each new data character is received (after reception has started).

Time-out duration = TO x 4 x Bit period

## USART Transmitter Time-guard Register

**Name:** US\_TTGR  
**Access Type:** Read/Write  
**Reset Value:** 0  
**Offset:** 0x28

31	30	29	28	27	26	25	24
–	–	–	–	–	–	–	–
23	22	21	20	19	18	17	16
–	–	–	–	–	–	–	–
15	14	13	12	11	10	9	8
–	–	–	–	–	–	–	–
7	6	5	4	3	2	1	0
TG							

- TG: Time-guard Value**

TG	
0	Disables the TX Time-guard function.
1 - 255	TXD is inactive high after the transmission of each character for the time-guard duration.

Time-guard duration = TG x Bit period

## USART Receive Pointer Register

**Name:** US\_RPR  
**Access Type:** Read/Write  
**Reset Value:** 0  
**Offset:** 0x30

31	30	29	28	27	26	25	24
RXPTR							
23	22	21	20	19	18	17	16
RXPTR							
15	14	13	12	11	10	9	8
RXPTR							
7	6	5	4	3	2	1	0
RXPTR							

- **RXPTR: Receive Pointer**  
RXPTR must be loaded with the address of the receive buffer.

## USART Receive Counter Register

**Name:** US\_RCR  
**Access Type:** Read/Write  
**Reset Value:** 0  
**Offset:** 0x34

31	30	29	28	27	26	25	24
—	—	—	—	—	—	—	—
23	22	21	4920	19	18	17	16
—	—	—	—	—	—	—	—
15	14	13	12	11	10	9	8
RXCTR							
7	6	5	4	3	2	1	0
RXCTR							

- **RXCTR: Receive Counter**  
RXCTR must be loaded with the size of the receive buffer.  
0: Stop Peripheral Data Transfer dedicated to the receiver.  
1 - 65535: Start Peripheral Data transfer if RXRDY is active.

## USART Transmit Pointer Register

**Name:** US\_TPR  
**Access Type:** Read/Write  
**Reset Value:** 0  
**Offset:** 0x38

31	30	29	28	27	26	25	24
TXPTR							
23	22	21	20	19	18	17	16
TXPTR							
15	14	13	12	11	10	9	8
TXPTR							
7	6	5	4	3	2	1	0
TXPTR							

- TXPTR: Transmit Pointer**  
 TXPTR must be loaded with the address of the transmit buffer.

## USART Transmit Counter Register

**Name:** US\_TCR  
**Access Type:** Read/Write  
**Reset Value:** 0  
**Offset:** 0x3C

31	30	29	28	27	26	25	24
—	—	—	—	—	—	—	—
23	22	21	20	19	18	17	16
—	—	—	—	—	—	—	—
15	14	13	12	11	10	9	8
TXCTR							
7	6	5	4	3	2	1	0
TXCTR							

- TXCTR: Transmit Counter**  
 TXCTR must be loaded with the size of the transmit buffer.  
 0: Stop Peripheral Data Transfer dedicated to the transmitter.  
 1 - 65535: Start Peripheral Data transfer if TXRDY is active.

## TC: Timer Counter

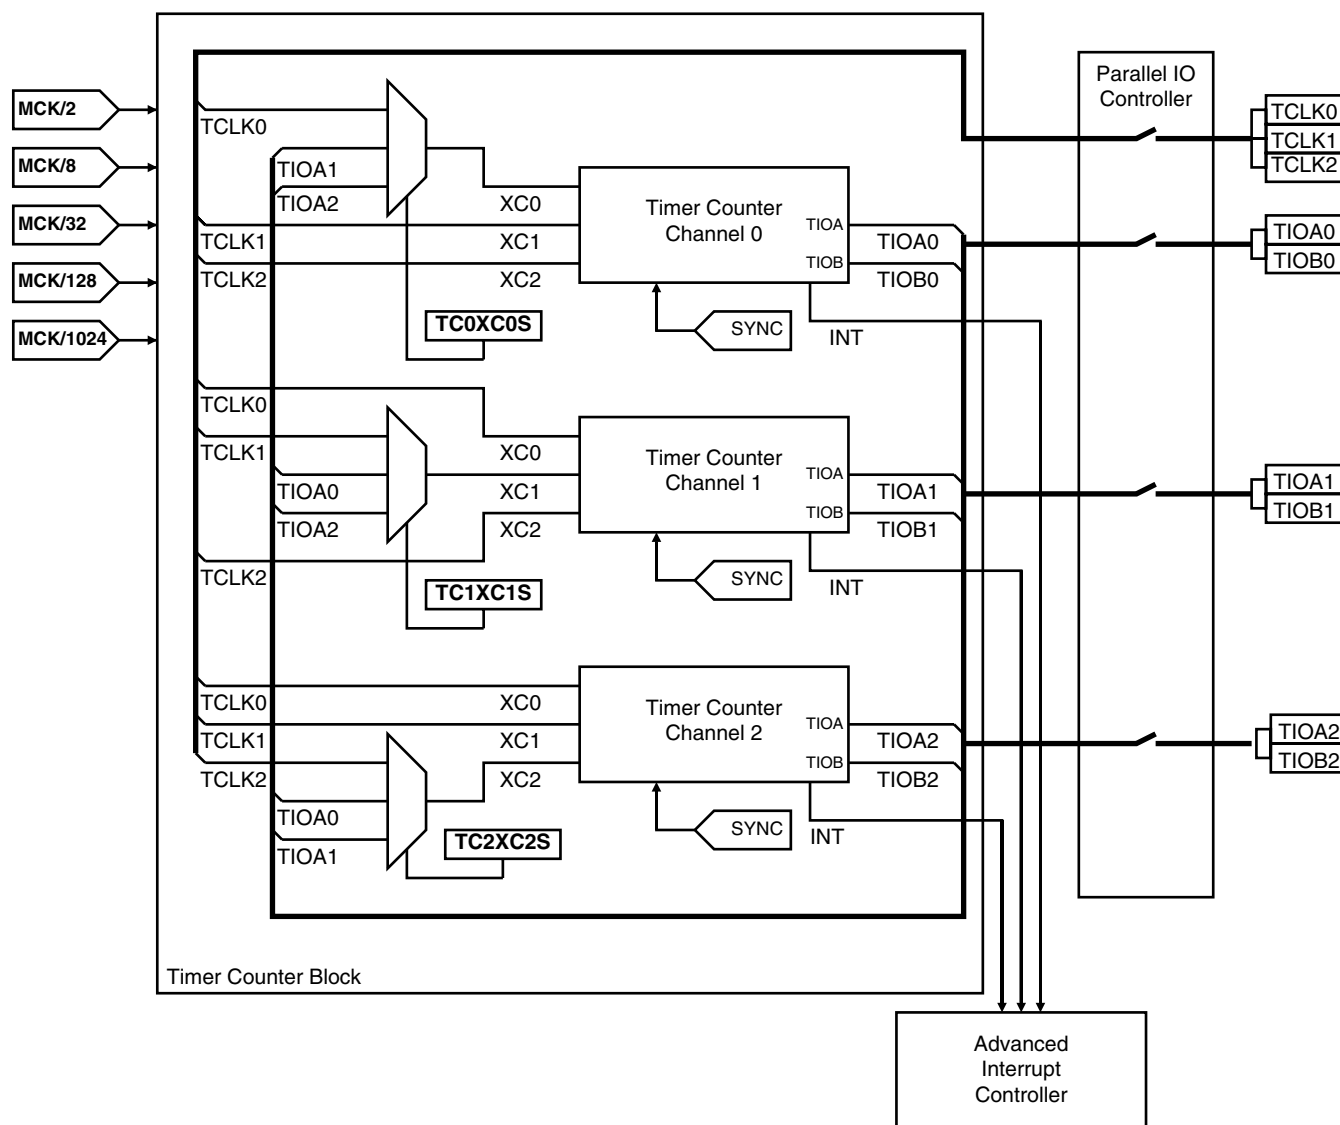

The AT91X40 Series features a Timer Counter block which includes three identical 16-bit timer counter channels. Each channel can be independently programmed to perform a wide range of functions including frequency measurement, event counting, interval measurement, pulse generation, delay timing and pulse width modulation.

Each Timer Counter channel has 3 external clock inputs, 5 internal clock inputs, and 2 multi-purpose input/output signals which can be configured by the user. Each channel

drives an internal interrupt signal which can be programmed to generate processor interrupts via the AIC (Advanced Interrupt Controller).

The Timer Counter block has two global registers which act upon all three TC channels. The Block Control Register allows the three channels to be started simultaneously with the same instruction. The Block Mode Register defines the external clock inputs for each Timer Counter channel, allowing them to be chained.

**Figure 43.** TC Block Diagram

## Signal Name Description

Channel Signal	Description
XC0, XC1, XC2	External Clock Inputs
TIOA	Capture Mode: General Purpose Input Waveform Mode: General Purpose Input
TIOB	Capture Mode: General Purpose Input Waveform Mode: General Purpose Input/Output
INT	Interrupt Signal Output
SYNC	Synchronization Input Signal
Block Signals	Description
TCLK0, TCLK1, TCLK2	External Clock Inputs
TIOA0	TIOA Signal for Channel 0
TIOB0	TIOB Signal for Channel 0
TIOA1	TIOA Signal for Channel 1
TIOB1	TIOB Signal for Channel 1
TIOA2	TIOA Signal for Channel 2
TIOB2	TIOB Signal for Channel 2

Note: After a hardware reset, the Timer Counter block pins are controlled by the PIO Controller. They must be configured to be controlled by the peripheral before being used.

## Timer Counter Description

The three Timer Counter channels are independent and identical in operation. The registers for channel programming are listed in Table 17.

### Counter

Each Timer Counter channel is organized around a 16-bit counter. The value of the counter is incremented at each positive edge of the selected clock. When the counter has reached the value 0xFFFF and passes to 0x0000, an overflow occurs and the bit COVFS in TC\_SR (Status Register) is set.

The current value of the counter is accessible in real-time by reading TC\_CV. The counter can be reset by a trigger. In this case, the counter value passes to 0x0000 on the next valid edge of the selected clock.

### Clock Selection

At block level, input clock signals of each channel can either be connected to the external inputs TCLK0, TCLK1 or TCLK2, or be connected to the configurable I/O signals TIOA0, TIOA1 or TIOA2 for chaining by programming the TC\_BMR (Block Mode).

Each channel can independently select an internal or external clock source for its counter:

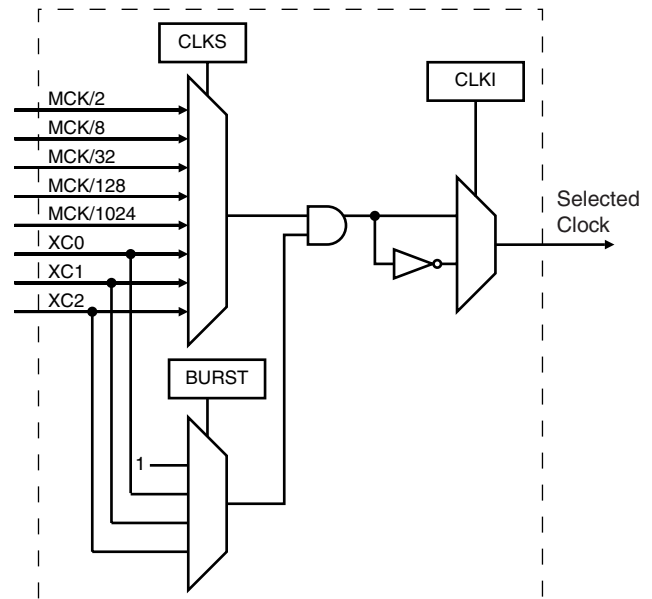

- Internal clock signals: MCK/2, MCK/8, MCK/32, MCK/128, MCK/1024
- External clock signals: XC0, XC1 or XC2

The selected clock can be inverted with the CLKI bit in TC\_CMR (Channel Mode). This allows counting on the opposite edges of the clock.

The burst function allows the clock to be validated when an external signal is high. The BURST parameter in the Mode Register defines this signal (none, XC0, XC1, XC2).

Note: In all cases, if an external clock is used, the duration of each of its levels must be longer than the system clock (MCK) period. The external clock frequency must be at least 2.5 times lower than the system clock (MCK).

**Figure 44.** Clock Selection

## Clock Control

The clock of each counter can be controlled in two different ways: it can be enabled/disabled and started/stopped.

- The clock can be **enabled** or **disabled** by the user with the CLKEN and the CLKDIS commands in the Control Register. In Capture Mode it can be disabled by an RB load event if LDBDIS is set to 1 in TC\_CMR. In Waveform Mode, it can be disabled by an RC Compare event if CPCDIS is set to 1 in TC\_CMR. When disabled, the start or the stop actions have no effect: only a CLKEN command in the Control Register can re-enable the clock. When the clock is enabled, the CLKSTA bit is set in the Status Register.
- The clock can also be **started** or **stopped**: a trigger (software, synchro, external or compare) always starts the clock. The clock can be stopped by an RB load event in Capture Mode (LDBSTOP = 1 in TC\_CMR) or a RC compare event in Waveform Mode (CPCSTOP = 1 in TC\_CMR). The start and the stop commands have effect only if the clock is enabled.

**Figure 45.** Clock Control

## Timer Counter Operating Modes

Each Timer Counter channel can independently operate in two different modes:

- Capture Mode allows measurement on signals
- Waveform Mode allows wave generation

The Timer Counter Operating Mode is programmed with the WAVE bit in the TC Mode Register. In Capture Mode, TIOA and TIOB are configured as inputs. In Waveform Mode, TIOA is always configured to be an output and TIOB is an output if it is not selected to be the external trigger.

## Trigger

A trigger resets the counter and starts the counter clock. Three types of triggers are common to both modes, and a fourth external trigger is available to each mode.

The following triggers are common to both modes:

- Software Trigger: Each channel has a software trigger, available by setting SWTRG in TC\_CCR.
- SYNC: Each channel has a synchronization signal SYNC. When asserted, this signal has the same effect as a software trigger. The SYNC signals of all channels are asserted simultaneously by writing TC\_BCR (Block Control) with SYNC set.
- Compare RC Trigger: RC is implemented in each channel and can provide a trigger when the counter value matches the RC value if CPCTRG is set in TC\_CMR.

The Timer Counter channel can also be configured to have an external trigger. In Capture Mode, the external trigger signal can be selected between TIOA and TIOB. In Waveform Mode, an external event can be programmed on one of the following signals: TIOB, XC0, XC1 or XC2. This external event can then be programmed to perform a trigger by setting ENETRIG in TC\_CMR.

If an external trigger is used, the duration of the pulses must be longer than the system clock (MCK) period in order to be detected.

Whatever the trigger used, it will be taken into account at the following active edge of the selected clock. This means that the counter value may not read zero just after a trigger, especially when a low frequency signal is selected as the clock.

## Capture Operating Mode

This mode is entered by clearing the WAVE parameter in TC\_CMR (Channel Mode Register). Capture Mode allows the TC Channel to perform measurements such as pulse timing, frequency, period, duty cycle and phase on TIOA and TIOB signals which are inputs.

Figure 46 shows the configuration of the TC Channel when programmed in Capture Mode.

### Capture Registers A and B (RA and RB)

Registers A and B are used as capture registers. This means that they can be loaded with the counter value when a programmable event occurs on the signal TIOA.

The parameter LDRA in TC\_CMR defines the TIOA edge for the loading of register A, and the parameter LDRB defines the TIOA edge for the loading of Register B.

RA is loaded only if it has not been loaded since the last trigger or if RB has been loaded since the last loading of RA.

RB is loaded only if RA has been loaded since the last trigger or the last loading of RB.

Loading RA or RB before the read of the last value loaded sets the Overrun Error Flag (LOVRS) in TC\_SR (Status Register). In this case, the old value is overwritten.

### Trigger Conditions

In addition to the SYNC signal, the software trigger and the RC compare trigger, an external trigger can be defined.

Bit ABETRG in TC\_CMR selects input signal TIOA or TIOB as an external trigger. Parameter ETRGEDG defines the edge (rising, falling or both) detected to generate an external trigger. If ETRGEDG = 0 (none), the external trigger is disabled.

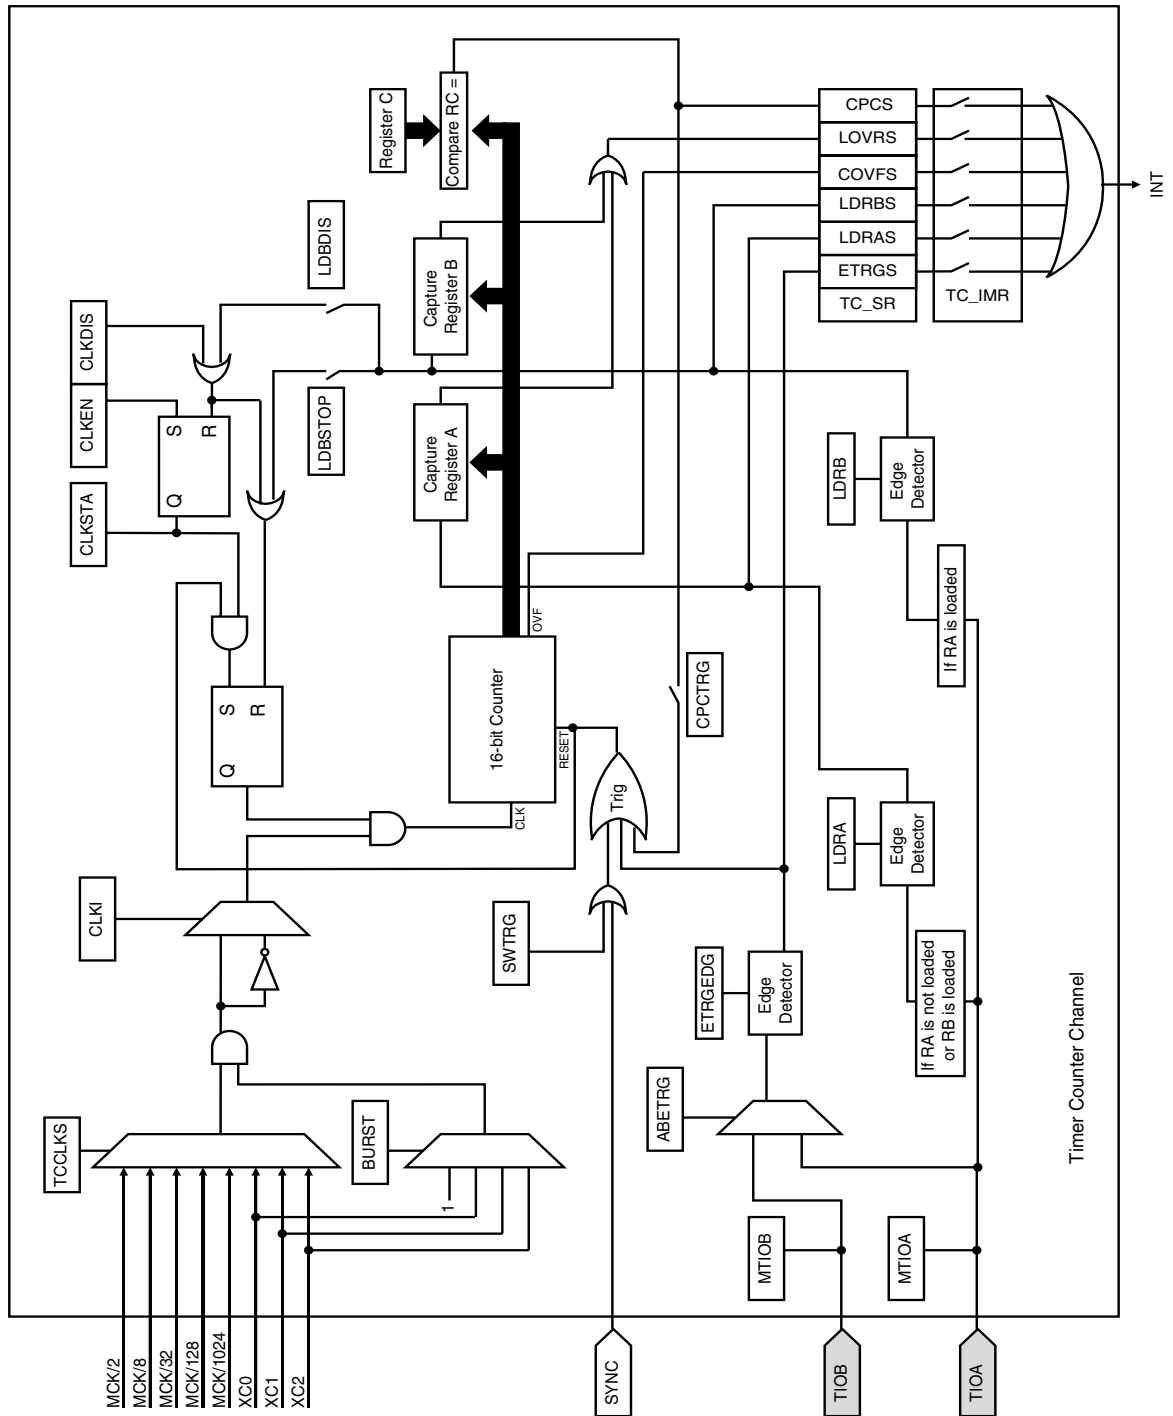

### Status Register

The following bits in the status register are significant in Capture Operating Mode.

- CPCS: RC Compare Status  
There has been an RC Compare match at least once since the last read of the status
- COVFS: Counter Overflow Status  
The counter has attempted to count past \$FFFF since the last read of the status
- LOVRS: Load Overrun Status  
RA or RB has been loaded at least twice without any read of the corresponding register, since the last read of the status
- LDRAS: Load RA Status  
RA has been loaded at least once without any read, since the last read of the status
- LDRBS: Load RB Status  
RB has been loaded at least once without any read, since the last read of the status
- ETRGS: External Trigger Status  
An external trigger on TIOA or TIOB has been detected since the last read of the status

Figure 46. Capture Mode

## Waveform Operating Mode

This mode is entered by setting the WAVE parameter in TC\_CMR (Channel Mode Register).

Waveform Operating Mode allows the TC Channel to generate 1 or 2 PWM signals with the same frequency and independently programmable duty cycles, or to generate different types of one-shot or repetitive pulses.

In this mode, TIOA is configured as output and TIOB is defined as output if it is not used as an external event (EEVT parameter in TC\_CMR).

Figure 47 shows the configuration of the TC Channel when programmed in Waveform Operating Mode.

### Compare Register A, B and C (RA, RB, and RC)

In Waveform Operating Mode, RA, RB and RC are all used as compare registers.

RA Compare is used to control the TIOA output. RB Compare is used to control the TIOB (if configured as output). RC Compare can be programmed to control TIOA and/or TIOB outputs.

RC Compare can also stop the counter clock (CPCSTOP = 1 in TC\_CMR) and/or disable the counter clock (CPCDIS = 1 in TC\_CMR).

As in Capture Mode, RC Compare can also generate a trigger if CPCTRG = 1. A trigger resets the counter so RC can control the period of PWM waveforms.

### External Event/Trigger Conditions

An external event can be programmed to be detected on one of the clock sources (XC0, XC1, XC2) or TIOB. The external event selected can then be used as a trigger.

The parameter EEVT in TC\_CMR selects the external trigger. The parameter EEVTEDG defines the trigger edge for each of the possible external triggers (rising, falling or both). If EEVTEDG is cleared (none), no external event is defined.

If TIOB is defined as an external event signal (EEVT = 0), TIOB is no longer used as output and the TC channel can only generate a waveform on TIOA.

When an external event is defined, it can be used as a trigger by setting bit ENETRIG in TC\_CMR.

As in Capture Mode, the SYNC signal, the software trigger and the RC compare trigger are also available as triggers.

### Output Controller

The output controller defines the output level changes on TIOA and TIOB following an event. TIOB control is used only if TIOB is defined as output (not as an external event).

The following events control TIOA and TIOB: software trigger, external event and RC compare. RA compare controls TIOA and RB compare controls TIOB. Each of these

events can be programmed to set, clear or toggle the output as defined in the corresponding parameter in TC\_CMR.

The tables below show which parameter in TC\_CMR is used to define the effect of each event.

Parameter	TIOA Event
ASWTRG	Software Trigger
AAEVT	External Event
ACPC	RC Compare
ACPA	RA Compare

Parameter	TIOB Event
BSWTRG	Software Trigger
BEEVT	External Event
BCPC	RC Compare
BCPB	RB Compare

If two or more events occur at the same time, the priority level is defined as follows:

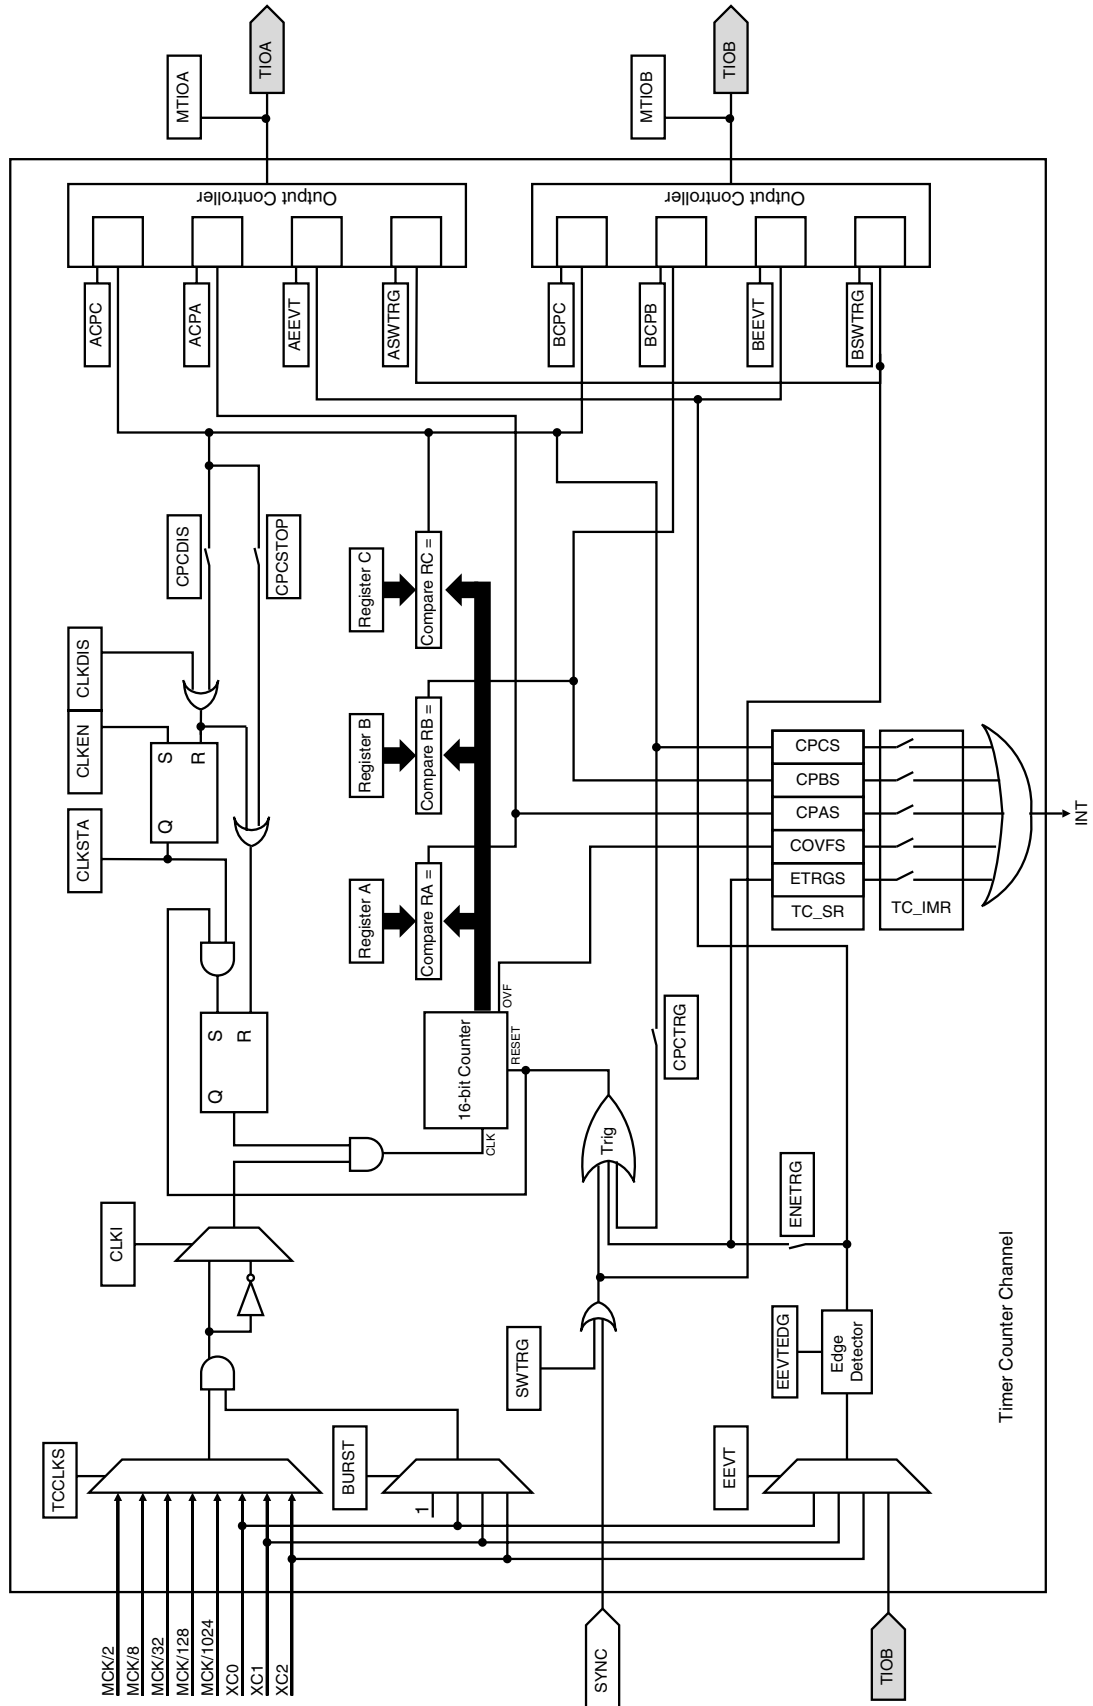

1. Software Trigger
2. External Event
3. RC Compare
4. RA or RB Compare

### Status

The following bits in the status register are significant in Waveform Mode:

- CPAS: RA Compare Status  
There has been a RA Compare match at least once since the last read of the status
- CPBS: RB Compare Status  
There has been a RB Compare match at least once since the last read of the status
- CPCS: RC Compare Status  
There has been a RC Compare match at least once since the last read of the status
- COVFS: Counter Overflow  
Counter has attempted to count past \$FFFF since the last read of the status
- ETRGS: External Trigger  
External trigger has been detected since the last read of the status

Figure 47. Waveform Mode

## TC User Interface

TC Base Address: 0xFFFE0000

**Table 16.** TC Global Memory Map

Offset	Channel/Register	Name	Access	Reset State
0x00	TC Channel 0	See Table 17		
0x40	TC Channel 1	See Table 17		
0x80	TC Channel 2	See Table 17		
0xC0	TC Block Control Register	TC_BCR	Write Only	–
0xC4	TC Block Mode Register	TC_BMR	Read/Write	0

TC\_BCR (Block Control Register) and TC\_BMR (Block Mode Register) control the TC block. TC Channels are controlled by the registers listed in Table 17. The offset of each of the Channel registers in Table 17 is in relation to the offset of the corresponding channel as mentioned in Table 16.

**Table 17.** TC Channel Memory Map

Offset	Register	Name	Access	Reset State
0x00	Channel Control Register	TC_CCR	Write Only	–
0x04	Channel Mode Register	TC_CMR	Read/Write	0
0x08	Reserved			–
0x0C	Reserved			–
0x10	Counter Value	TC_CV	Read/Write	0
0x14	Register A	TC_RA	Read/Write <sup>(1)</sup>	0
0x18	Register B	TC_RB	Read/Write <sup>(1)</sup>	0
0x1C	Register C	TC_RC	Read/Write	0
0x20	Status Register	TC_SR	Read Only	0
0x24	Interrupt Enable Register	TC_IER	Write Only	–
0x28	Interrupt Disable Register	TC_IDR	Write Only	–
0x2C	Interrupt Mask Register	TC_IMR	Read Only	0

Note: Read only if WAVE = 0

## TC Block Control Register

**Register Name:** TC\_BCR  
**Access Type:** Write only  
**Offset:** 0xC0

31	30	29	28	27	26	25	24
—	—	—	—	—	—	—	—
23	22	21	20	19	18	17	16
—	—	—	—	—	—	—	—
15	14	13	12	11	10	9	8
—	—	—	—	—	—	—	—
7	6	5	4	3	2	1	0
—	—	—	—	—	—	—	SYNC

- SYNC: Synchro Command**

0 = No effect.

1 = Asserts the SYNC signal which generates a software trigger simultaneously for each of the channels.

## TC Block Mode Register

**Register Name:** TC\_BMR  
**Access Type:** Read/Write  
**Reset Value:** 0  
**Offset:** 0xC4

31	30	29	28	27	26	25	24

1	1	TIOA2

- **TC1XC1S: External Clock Signal 1 Selection**

TC1XC1S		Signal Connected to XC1
0	0	TCLK1
0	1	None
1	0	TIOA0
1	1	TIOA2

- **TC2XC2S: External Clock Signal 2 Selection**

TC2XC2S		Signal Connected to XC2
0	0	TCLK2
0	1	None
1	0	TIOA0
1	1	TIOA1

## TC Channel Control Register

**Register Name:** TC\_CCR  
**Access Type:** Write only  
**Offset:** 0x00

31	30	29	28	27	26	25	24
–	–	–	–	–	–	–	–
23	22	21	20	19	18	17	16
–	–	–	–	–	–	–	–
15	14	13	12	11	10	9	8
–	–	–	–	–	–	–	–
7	6	5	4	3	2	1	0
–	–	–	–	–	SWTRG	CLKDIS	CLKEN

- **CLKEN: Counter Clock Enable Command**  
 0 = No effect.  
 1 = Enables the clock if CLKDIS is not 1.
- **CLKDIS: Counter Clock Disable Command**  
 0 = No effect.  
 1 = Disables the clock.
- **SWTRG: Software Trigger Command**  
 0 = No effect.  
 1 = A software trigger is performed: the counter is reset and clock is started.

## TC Channel Mode Register: Capture Mode

**Register Name:** TC\_CMCR  
**Access Type:** Read/Write  
**Reset Value:** 0  
**Offset:** 0x04

31	30	29	28	27	26	25	24

TCCLKS			Clock Selected
0	0	0	MCK/2
0	0	1	MCK/8
0	1	0	MCK/32
0	1	1	MCK/128
1	0	0	MCK/1024
1	0	1	XC0
1	1	0	XC1
1	1	1	XC2

- CLKI: Clock Invert**

0 = Counter is incremented on rising edge of the clock.  
 1 = Counter is incremented on falling edge of the clock.

- BURST: Burst Signal Selection**

BURST		
0	0	The clock is not gated by an external signal
0	1	XC0 is ANDed with the selected clock
1	0	XC1 is ANDed with the selected clock
1	1	XC2 is ANDed with the selected clock

- LDBSTOP: Counter Clock Stopped with RB Loading**

0 = Counter clock is not stopped when RB loading occurs.  
 1 = Counter clock is stopped when RB loading occurs.

- LDBDIS: Counter Clock Disable with RB Loading**

0 = Counter clock is not disabled when RB loading occurs.  
 1 = Counter clock is disabled when RB loading occurs.

- **ETRGEDG: External Trigger Edge Selection**

ETRGEDG		Edge
0	0	None
0	1	Rising Edge
1	0	Falling Edge
1	1	Each Edge

- **ABETRG: TIOA or TIOB External Trigger Selection**

0 = TIOB is used as an external trigger.

1 = TIOA is used as an external trigger.

- **CPCTRG: RC Compare Trigger Enable**

0 = RC Compare has no effect on the counter and its clock.

1 = RC Compare resets the counter and starts the counter clock.

- **WAVE = 0**

0 = Capture Mode is enabled.

1 = Capture Mode is disabled (Waveform Mode is enabled).

- **LDRA: RA Loading Selection**

LDRA		Edge
0	0	None
0	1	Rising Edge of TIOA
1	0	Falling Edge of TIOA
1	1	Each Edge of TIOA

- **LDRB: RB Loading Selection**

LDRB		Edge
0	0	None
0	1	Rising Edge of TIOA
1	0	Falling Edge of TIOA
1	1	Each Edge of TIOA

## TC Channel Mode Register: Waveform Mode

**Register Name:** TC\_CMCR  
**Access Type:** Read/Write  
**Reset Value:** 0  
**Offset:** 0x04

31	30	29	28	27	26	25	24
BSWTRG		BEEVT		BCPC		BCPB	
23	22	21	20	19	18	17	16

						TCCLKS	

### • TCCLKS: Clock Selection

TCCLKS			Clock Selected
0	0	0	MCK/2
0	0	1	MCK/8
0	1	0	MCK/32
0	1	1	MCK/128
1	0	0	MCK/1024
1	0	1	XC0
1	1	0	XC1
1	1	1	XC2

### • CLKI: Clock Invert

0 = Counter is incremented on rising edge of the clock.  
 1 = Counter is incremented on falling edge of the clock.

### • BURST: Burst Signal Selection

BURST		
0	0	The clock is not gated by an external signal.
0	1	XC0 is ANDed with the selected clock.
1	0	XC1 is ANDed with the selected clock.
1	1	XC2 is ANDed with the selected clock.

### • CPCSTOP: Counter Clock Stopped with RC Compare

0 = Counter clock is not stopped when counter reaches RC.  
 1 = Counter clock is stopped when counter reaches RC.

### • CPCDIS: Counter Clock Disable with RC Compare

0 = Counter clock is not disabled when counter reaches RC.  
 1 = Counter clock is disabled when counter reaches RC.

- **EEVTEG: External Event Edge Selection**

EEVTEG		Edge
0	0	None
0	1	Rising Edge
1	0	Falling Edge
1	1	Each Edge

- **EEVT: External Event Selection**

EEVT		Signal Selected as External Event	TIOB Direction
0	0	TIOB	Input <sup>(1)</sup>
0	1	XC0	Output
1	0	XC1	Output
1	1	XC2	Output

Note: If TIOB is chosen as the external event signal, it is configured as an input and no longer generates waveforms.

- **ENETR: External Event Trigger Enable**

0 = The external event has no effect on the counter and its clock. In this case, the selected external event only controls the TIOA output.

1 = The external event resets the counter and starts the counter clock.

- **CPCTR: RC Compare Trigger Enable**

0 = RC Compare has no effect on the counter and its clock.

1 = RC Compare resets the counter and starts the counter clock.

- **WAVE = 1**

0 = Waveform Mode is disabled (Capture Mode is enabled).

1 = Waveform Mode is enabled.

- **ACPA: RA Compare Effect on TIOA**

ACPA		Effect
0	0	None
0	1	Set
1	0	Clear
1	1	Toggle

- **ACPC: RC Compare Effect on TIOA**

ACPC		Effect
0	0	None
0	1	Set

## TC Counter Value Register

**Register Name:** TC\_CVR  
**Access Type:** Read only  
**Reset Value:** 0  
**Offset:** 0x10

31	30	29	28	27	26	25	24
–	–	–	–	–	–	–	–
23	22	21	20	19	18	17	16
–	–	–	–	–	–	–	–
15	14	13	12	11	10	9	8
CV							
7	6	5	4	3	2	1	0
CV							

- **CV: Counter Value**  
CV contains the counter value in real-time.

## TC Register A

**Register Name:** TC\_RA  
**Access Type:** Read only if WAVE = 0, Read/Write if WAVE = 1  
**Reset Value:** 0  
**Offset:** 0x14

31	30	29	28	27	26	25	24
–	–	–	–	–	–	–	–
23	22	21	20	19	18	17	16
–	–	–	–	–	–	–	–
15	14	13	12	11	10	9	8
RA							
7	6	5	4	3	2	1	0
RA							

- **RA: Register A**  
RA contains the Register A value in real-time.

## TC Register B

**Register Name:** TC\_RB  
**Access Type:** Read only if WAVE = 0, Read/Write if WAVE = 1  
**Reset Value:** 0  
**Offset:** 0x18

31	30	29	28	27	26	25	24
–	–	–	–	–	–	–	–
23	22	21	20	19	18	17	16
–	–	–	–	–	–	–	–
15	14	13	12	11	10	9	8
RB							
7	6	5	4	3	2	1	0
RB							

- **RB: Register B**  
RB contains the Register B value in real-time.

## TC Register C

**Register Name:** TC\_RC  
**Access Type:** Read/Write  
**Reset Value:** 0  
**Offset:** 0x1C

31	30	29	28	27	26	25	24
–	–	–	–	–	–	–	–
23	22	21	20	19	18	17	16
–	–	–	–	–	–	–	–
15	14	13	12	11	10	9	8
RC							
7	6	5	4	3	2	1	0
RC							

- **RC: Register C**  
RC contains the Register C value in real-time.

## TC Status Register

**Register Name:** TC\_SR  
**Access Type:** Read only  
**Reset Value:** 0  
**Offset:** 0x20

31	30	29	28	27	26	25	24
–	–	–	–	–	–	–	–
23	22	21	20	19	18	17	16
–	–	–	–	–	MTIOB	MTIOA	CLKSTA
15	14	13	12	11	10	9	8
–	–	–	–	–	–	–	–
7	6	5	4	3	2	1	0
ETRGS	LDRBS	LDRAS	CPCS	CPBS	CPAS	LOVRS	COVFS

- COVFS: Counter Overflow Status**  
 0 = No counter overflow has occurred since the last read of the Status Register.  
 1 = A counter overflow has occurred since the last read of the Status Register.
- LOVRS: Load Overrun Status**  
 0 = Load overrun has not occurred since the last read of the Status Register or WAVE = 1.  
 1 = RA or RB have been loaded at least twice without any read of the corresponding register since the last read of the Status Register, if WAVE = 0.
- CPAS: RA Compare Status**  
 0 = RA Compare has not occurred since the last read of the Status Register or WAVE = 0.  
 1 = RA Compare has occurred since the last read of the Status Register, if WAVE = 1.
- CPBS: RB Compare Status**  
 0 = RB Compare has not occurred since the last read of the Status Register or WAVE = 0.  
 1 = RB Compare has occurred since the last read of the Status Register, if WAVE = 1.
- CPCS: RC Compare Status**  
 0 = RC Compare has not occurred since the last read of the Status Register.  
 1 = RC Compare has occurred since the last read of the Status Register.
- LDRAS: RA Loading Status**  
 0 = RA Load has not occurred since the last read of the Status Register or WAVE = 1.  
 1 = RA Load has occurred since the last read of the Status Register, if WAVE = 0.
- LDRBS: RB Loading Status**  
 0 = RB Load has not occurred since the last read of the Status Register or WAVE = 1.  
 1 = RB Load has occurred since the last read of the Status Register, if WAVE = 0.
- ETRGS: External Trigger Status**  
 0 = External trigger has not occurred since the last read of the Status Register.  
 1 = External trigger has occurred since the last read of the Status Register.
- CLKSTA: Clock Enabling Status**  
 0 = Clock is disabled.  
 1 = Clock is enabled.
- MTIOA: TIOA Mirror**  
 0 = TIOA is low. If WAVE = 0, this means that TIOA pin is low. If WAVE = 1, this means that TIOA is driven low.  
 1 = TIOA is high. If WAVE = 0, this means that TIOA pin is high. If WAVE = 1, this means that TIOA is driven high.
- MTIOB: TIOB Mirror**  
 0 = TIOB is low. If WAVE = 0, this means that TIOB pin is low. If WAVE = 1, this means that TIOB is driven low.  
 1 = TIOB is high. If WAVE = 0, this means that TIOB pin is high. If WAVE = 1, this means that TIOB is driven high.

## TC Interrupt Enable Register

**Register Name:** TC\_IER  
**Access Type:** Write only  
**Offset:** 0x24

31	30	29	28	27	26	25	24
