

LB1928

Three-Phase Brushless Motor Driver for Office Automation Equipment

Overview

The LB1928 is a 3-phase brushless motor driver well suited for drum and paper feed motors in laser printers, plain-paper copiers and other office automation equipment. Direct PWM drive allows control with low power losses. Peripheral circuitry including speed control circuit and FG amplifier is integrated, thus allows drive circuit to be constructed with a single chip.

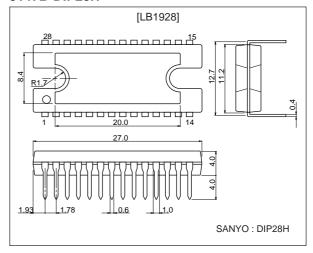

Functions and Features

- Three-phase bipolar drive (30V, 3.1A)
- Direct PWM drive technique
- Built-in diode for absorbing output lower-side kickback
- Speed discriminator and PLL speed control
- · Speed lock detection output
- Built-in forward/reverse switching circuit
- Built-in protection circuitry includes current limiter, overheat protection, motor restraint protection, etc.

Package Dimensions

unit: mm

3147B-DIP28H

Specifications

Absolute Maximum Ratings at $Ta = 25^{\circ}C$

Parameter	Symbol	Conditions	Ratings	Unit
Maximum supply voltage	Vcc max		30	V
Maximum output current	I _O max	T ≤ 500 ms	3.1	А
Allowable power dissipation 1	Pd max 1	IC only	3	W
Allowable power dissipation 2	Pd max 2	With an arbitrary large heat sink	20	W
Operating temperature	Topr		-20 to +80	°C
Storage temperature	Tstg		-55 to +150	°C

Allowable Operating Ranges at $Ta = 25^{\circ}C$

Parameter	Symbol	Conditions	Ratings	Unit
Power supply voltage range 1	Vcc		9.5 to 28	V
Regulator voltage output current	I _{REG}		0 to -20	mA
LD output current	I _{LD}		0 to 15	mA

- Any and all SANYO products described or contained herein do not have specifications that can handle applications that require extremely high levels of reliability, such as life-support systems, aircraft's control systems, or other applications whose failure can be reasonably expected to result in serious physical and/or material damage. Consult with your SANYO representative nearest you before using any SANYO products described or contained herein in such applications.
- SANYO assumes no responsibility for equipment failures that result from using products at values that exceed, even momentarily, rated values (such as maximum ratings, operating condition ranges, or other parameters) listed in products specifications of any and all SANYO products described or contained herein.

Description of the LB1928

1. Speed control circuit

The IC performs speed control through combined use of a speed discrimination circuit and PLL circuit. The speed control circuit counts FG cycles and outputs a deviation signal every 2 FG cycles. The PLL circuit outputs a phase deviation signal every FG cycle.

The FG servo frequency is determined by the following equation. The motor rotation speed is set by the number of FG pulses and the crystal oscillator frequency.

fFG (servo) = fOSC/8192

fOSC: Crystal oscillator frequency

2. Output drive circuit

In order to reduce power loss at the output, the LB1928 uses the PWM drive technique. While ON, the output transistors are always saturated, and motor drive power is adjusted by varying the output ON duty ratio. Because output PWM switching is performed by the lower-side output transistor, a Schottky diode must be connected between OUT and V_{CC} . (If the reverse recovery time of the diode is too long, a feedthrough current will flow at the instant when the lower-side transistor goes ON.) An internal diode is provided between OUT and GND. If large output current causes a problem (waveform distortion during lower-side kickback, etc.), an external rectifying diode or Schottky diode should be connected.

The output diode is integrated only on the lower side.

3. Current limiting circuit

The current limiting circuit limits the peak current to the value I = VRF/Rf (VRF = 0.5 V typ., Rf: current detector resistance). Current limiting is achieved by reducing the ON duty ratio of the output, which reduces the current.

4. Power save circuit

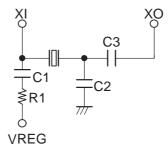

In order to reduce current drain in the STOP condition, the IC goes into power save mode. In this condition, bias current to most circuits is cut off, but the 5V regulator output remains active.

5. Reference clock

The reference clock for speed control can be input using one of the following two methods.

[1] Using a crystal oscillator

When a crystal is used for oscillation, connect the crystal, capacitors, and a resistor as shown in the figure below.

C1, R1: For stable oscillation

C3: For crystal coupling

C2: For overtone oscillation prevention

(Reference values)

Oscillator frequency (MHz)	C1 (μF)	C2 (pF)	C3 (pF)	R1 (Ω)
3 to 5	0.1	10	47	330k
5 to 8	0.1	None	47	330k
8 to 10	0.1	None	22	330k

The circuit configuration and values are for reference only. The crystal oscillator's characteristics as well as the possibility of floating capacitance and noise due to layout factors must be taken into consideration when designing an actual application.

[Precautions for wiring layout design]

Since the crystal oscillator circuit operates at high frequencies, it is susceptible to the influence of floating capacitance from the circuit board. Wiring should be kept as short as possible and traces should be kept narrow.

When designing the external circuitry, pay special attention to the wiring layout between the oscillator and C3 (C2), to minimize the influence of floating capacitance.

[2] External clock input (equivalent to crystal oscillator, several MHz)

When using an external signal source instead of a crystal oscillator, the clock signal should be input from the XO pin through a resistor of about 5.1 k Ω connected to the pin in series. The XO pin should be left open. Signal input level

Low: 0 to 0.8V High: 2.5 to 5.0V

6. Speed lock range

The speed clock range is $\pm 6.25\%$ of the rated speed. When the motor rotation is within the lock range, the LD pin becomes Low (open collector output). When the motor rotation goes out of the lock range, the ON duty ratio of the motor drive output is varied according to the amount of deviation to bring the rotation back into the lock range.

7. PWM frequency

The PWM frequency is determined by the capacitance connected to the PWM pin.

 $f PWM = 1/(14400 \times C)$

The PWM frequency should be between 15 and 25 kHz.

8. Hall input signal

The Hall input requires a signal with an amplitude of at least the hysteresis width (42 mV max.). Taking possible noise influences into consideration, an amplitude of at least 100 mV is desirable.

9. Forward/reverse switching

Forward/reverse switching of motor rotation is carried out with the F/R pin. If this is performed while the motor is running, the following points must be observed:

- Feedthrough current during switching is handled by proper circuit design. However, the V_{CC} voltage rise
 during switching (caused by momentary return of motor current to power supply) must not exceed the rated
 voltage (30V). If problems occur, the capacitance between V_{CC} and GND must be increased.
- If the motor current after switching exceeds the current limiter value, the lower-side transistors go OFF but the upper-side transistors go into the short brake state, which causes a current flow. The magnitude of the current is determined by the motor counterelectromotive voltage and the coil resistance. This current may not exceed the rated current (3.1A). (Forward/reverse switching at high speed therefore is not safe.)

10. Motor restraint protection circuit

To protect the IC and the motor itself when rotation is inhibited, a restraint protection circuit is provided. If the LD output is High (unlocked) for a certain interval in the start condition, the lower-side transistors are turned off. The length of the interval is determined by the capacitance at the CSD pin. A capacitance of $10 \,\mu\text{F}$ results in a set interval of about 3.3 seconds. (Tolerance approx. $\pm 30\%$)

Set interval (s)
$$\doteq 0.33 \times C (\mu F)$$

If the capacitor arrangement is subject to leak current, possible adverse effects such as setting time tolerances must be taken into consideration.

When the restraint protection circuit has been activated, the condition can only be canceled by setting the system to the stop condition or by turning the power off and on again (in the stop condition). When wishing not to use the restraint protection circuit, connect the CSD pin to ground.

If the stop time when releasing the restraint protection is short, the capacitor charge will not be fully dissipated. This in turn will cause a shorter restraint protection activation time after the motor has been restarted. The stop time should therefore be designed to be sufficiently long, using the equation shown below (also when restarting in the motor start transient state).

Stop time (ms) $\geq 15 \times C (\mu F)$

11. Power supply regulation

Because this IC has a high output current, power supply line fluctuations can occur easily. Therefore a capacitor of sufficient capacitance must be connected between the V_{CC} pin and ground to assure stable operation. If a diode is used in the power line for reverse-connection protection, the likelihood of power line fluctuations increases further, which will require more capacitance.

- Specifications of any and all SANYO products described or contained herein stipulate the performance, characteristics, and functions of the described products in the independent state, and are not guarantees of the performance, characteristics, and functions of the described products as mounted in the customer's products or equipment. To verify symptoms and states that cannot be evaluated in an independent device, the customer should always evaluate and test devices mounted in the customer's products or equipment.
- SANYO Electric Co., Ltd. strives to supply high-quality high-reliability products. However, any and all semiconductor products fail with some probability. It is possible that these probabilistic failures could give rise to accidents or events that could endanger human lives, that could give rise to smoke or fire, or that could cause damage to other property. When designing equipment, adopt safety measures so that these kinds of accidents or events cannot occur. Such measures include but are not limited to protective circuits and error prevention circuits for safe design, redundant design, and structural design.
