

## High Speed, Precision, JFET Input Instrumentation Amplifier (Fixed Gain = 10 or 100)

### FEATURES

- Slew Rate
- Gain-Bandwidth Product
- Settling Time (0.01%)
- Overdrive Recovery
- Gain Error
- Gain Drift
- Gain Non-Linearity
- Offset Voltage (Input + Output)
  - Drift with Temperature
- Input Bias Current
- Input Offset Current
  - Drift with Temperature (to 70°C)

30V/ $\mu$ s
35MHz
3 $\mu$ s
0.4 $\mu$ s
0.05% Max
5ppm/ $^{\circ}$ C
16ppm Max
600 $\mu$ V Max
2.5 $\mu$ V/ $^{\circ}$ C
40pA Max
40pA Max
0.5pA/ $^{\circ}$ C

### APPLICATIONS

- Fast Settling Analog Signal Processing
- Multiplexed Input Data Acquisition Systems
- High Source Impedance Signal Amplification from High Resistance Bridges, Capacitance Sensors, Photodetector Sensors
- Bridge Amplifier with <1Hz Lowpass Filtering

### DESCRIPTION

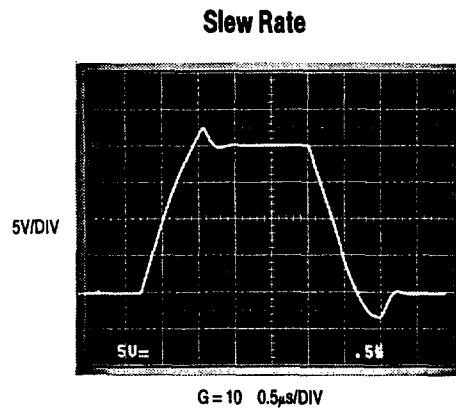

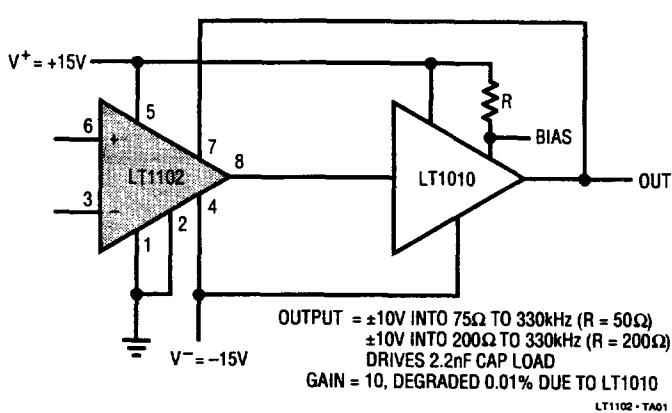

The LT1102 is the first fast FET input instrumentation amplifier offered in the low cost, space saving 8-pin packages. Fixed gains of 10 and 100 are provided with excellent gain accuracy (0.01%) and non-linearity (3ppm). No external gain setting resistor is required.

Slew rate, settling time, gain-bandwidth product, overdrive recovery time are all improved compared to competitive high speed instrumentation amplifiers.

Industry best speed performance is combined with impressive precision specifications: less than 10pA input bias and offset currents, 200 $\mu$ V offset voltage. Unlike other FET input instrumentation amplifiers, on the LT1102 there is no output offset voltage contribution to total error, and input bias currents do not double with every 10 $^{\circ}$ C rise in temperature. Indeed, at 70°C ambient temperature the input bias current is only 50pA.

3

Note 1: This parameter is tested on a sample basis only.

Note 2: Current noise is calculated from the formula:

$$i_n = (2qI_b)^{1/2}$$

where  $q = 1.6 \times 10^{-19}$  coulomb. The noise of source resistors up to  $1G\Omega$  swamps the contribution of current noise.

Note 3: This parameter is not tested. It is guaranteed by design and by inference from the slew rate measurement.

Note 4: Overdrive recovery is defined as the time delay from the removal of an input overdrive to the output's return from saturation to linear operation. 50% overdrive equals  $V_{IN} = \pm 2V$  ( $G = 10$ ) or  $V_{IN} = \pm 200mV$  ( $G = 100$ ).

Note 5: This parameter is not tested. It is guaranteed by design and by inference from other tests.

## TYPICAL PERFORMANCE CHARACTERISTICS

## TYPICAL PERFORMANCE CHARACTERISTICS

## APPLICATIONS INFORMATION

In the two op amp instrumentation amplifier configuration, the first amplifier is basically in unity gain, and the second amplifier provides all the voltage gain. In the LT1102 the second amplifier is decompensated for gain of 10 stability, therefore high slew rate and bandwidth are achieved. Common mode rejection versus frequency is also optimized in the  $G = 10$  mode, because the bandwidths of the two op amps are similar. When  $G = 100$  this statement is no longer true. However, by connecting an 18pF capacitor between pins 1 and 2, a common mode AC gain is created to cancel the inherent roll-off. From 200Hz to 30kHz CMRR versus frequency is improved by an order of magnitude.

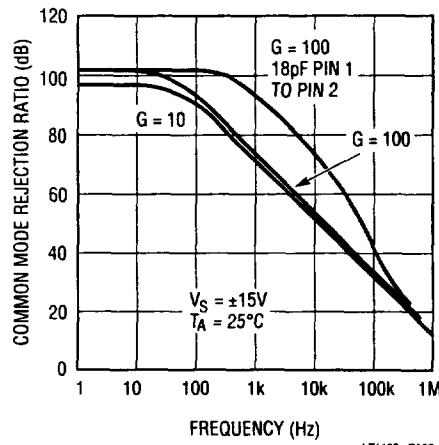

### Input Protection

Instrumentation amplifiers are often used in harsh environments where overload conditions can occur. The LT1102 employs FET input transistors, consequently the differential input voltage can be  $\pm 30V$  (with  $\pm 15V$  supplies,  $\pm 36V$  with  $\pm 18V$  supplies). Some competitive instrumentation amplifiers have NPN inputs which are protected by back to back diodes. When the differential input voltage exceeds  $\pm 1.3V$  on these competitive devices, input current increases to milliampere level; more than  $\pm 10V$  differential voltage can cause permanent damage.

When the LT1102 inputs are pulled below the negative supply or above the positive supply, the inputs will clamp a diode voltage below or above the supplies. No damage will occur if the input current is limited to 20mA.

3

### Common Mode Rejection Ratio vs Frequency

### Gains Between 10 and 100

Gains between 10 and 100 can be achieved by connecting two equal resistors ( $=R_x$ ) between pins 1 and 2 and pins 7 and 8.

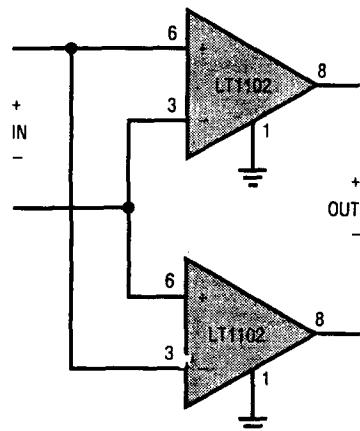

$$\text{Gain} = 10 + \frac{R_x}{R + R_x/90}$$

The nominal value of R is  $1.84k\Omega$ . The usefulness of this method is limited by the fact that R is not controlled to better than  $\pm 10\%$  absolute accuracy in production. However, on any specific unit 90R can be measured between pins 1 and 2.

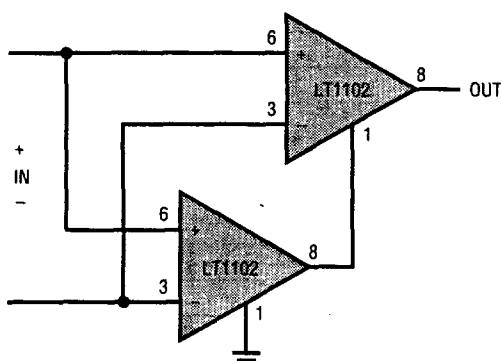

## APPLICATIONS INFORMATION

**Gain = 20, 110, or 200 Instrumentation Amplifiers**

### Differential Output

### Single Ended Output

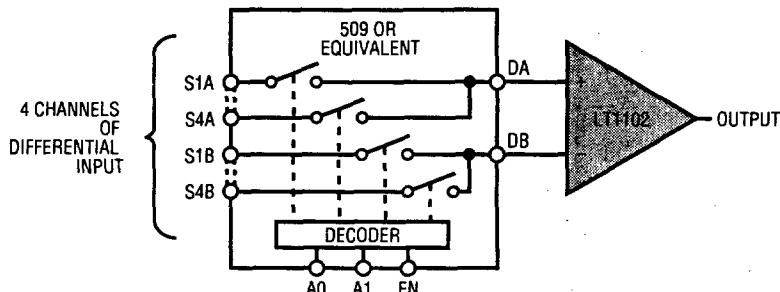

GAIN = 200, AS SHOWN

GAIN = 20, SHORT PIN 1 TO PIN 2, PIN 7 TO PIN 8 ON BOTH DEVICES

GAIN = 110, SHORT PIN 1 TO PIN 2, PIN 7 TO PIN 8 ON ONE DEVICE, NOT ON THE OTHER  
INPUT REFERRED NOISE IS REDUCED BY  $\sqrt{2}$  (G = 200 OR 20)
