SLAS227A – OCTOBER 1999 – REVISED JUNE 2000

- Low Supply Voltage Range 2.5 V 5.5 V
- Low Operation Current, 400 μA at 1 MHz, 3 V
- Ultralow-Power Consumption:
 - Standby Mode: 2 μA
 - RAM Retention Off Mode: 0.1 μA
- Five Power-Saving Modes
- Wake-Up From Standby Mode in 6 μs
- 16-Bit RISC Architecture, 300 ns Instruction Cycle Time
- Single Common 32 kHz Crystal, Internal System Clock up to 3.8 MHz
- Integrated LCD Driver for up to 120 Segments
- Integrated Hardware Multiplier Performs Signed, Unsigned on Multiply, and MAC Operations for Operands up to 16 × 16 Bits
- Serial Communication Interface (USART), Select Asynchronous UART or Synchronous SPI by Software

- Slope A/D Converter Using External Components
- 16-Bit Timer With Five Capture/Compare Registers
- Serial Onboard Programming
- Programmable Code Protection by Security Fuse
- Family Members Include:
 - MSP430C336 24 KB ROM, 1 KB RAM
 - MSP430C337 32 KB ROM, 1 KB RAM
 - MSP430P337A 32 KB OTP, 1 KB RAM
- EPROM Version Available for Prototyping:
 PMS430E337A
- Available in the Following Packages:
 - 100 Pin Quad Flat-Pack (QFP)
 - 100 Pin Ceramic Quad Flat-Pack (CFP) (EPROM Version)

description

The Texas Instruments MSP430 is an ultralow-power mixed signal microcontroller family consisting of several devices featuring different sets of modules targeted to various applications. The controller is designed to be battery-operated for an extended application lifetime. With the 16-bit RISC architecture, 16 integrated registers on the CPU, and a constant generator, the MSP430 achieves maximum code efficiency. The digital-controlled oscillator, together with the frequency lock loop (FLL), provides a wake-up from a low-power mode to an active mode in less than 6 µs. The MSP430x33x series microcontrollers have built-in hardware multiplication and communication capability using asynchronous (UART) and synchronous protocols.

Typical applications of the MSP430 family include electronic gas, water, and electric meters and other sensor systems that capture analog signals, convert them to digital values, process, displays, or transmits data to a host system.

Terminal Functions

TERMINAL		1/0	DESCRIPTION				
NAME	NO.	1/0	DESCRIPTION				
CIN	2	I	Input port. CIN is used as an enable for counter TPCNT1 – (Timer/Port).				
COM0-3	56–53	0	Common outputs. COM0-3 are used for LCD backplanes – LCD				
P0.0	9	I/O	General-purpose digital I/O				
P0.1/RXD	10	I/O	General-purpose digital I/O, receive digital Input port – 8-Bit Timer/Counter				
P0.2/TXD	11	I/O	General-purpose digital I/O, transmit data output port – 8-Bit Timer/Counter				
P0.3–P0.7	12–16	I/O	Five general-purpose digital I/Os, bit 3-7				
P1.0–P1.7	17–24	I/O	Eight general-purpose digital I/Os, bit 0-7				
P2.0–P2.7	25–27, 31–35	I/O	Eight general-purpose digital I/Os, bit 0-7				
P3.0, P3.1	36,37	I/O	Two general-purpose digital I/Os, bit 0 and bit 1				
P3.2/TACLK	38	I/O	General-purpose digital I/O, clock input – Timer_A				
P3.3/TA0	39	I/O	General-purpose digital I/O, capture I/O, or PWM output port – Timer_A CCR0				
P3.4/TA1	40	I/O	General-purpose digital I/O, capture I/O, or PWM output port – Timer_A CCR1				
P3.5/TA2	41	I/O	General-purpose digital I/O, capture I/O, or PWM output port – Timer_A CCR2				
P3.6/TA3	42	I/O	General-purpose digital I/O, capture I/O, or PWM output port – Timer_A CCR3				
P3.7/TA4	43	I/O	General-purpose digital I/O, capture I/O, or PWM output port – Timer_A CCR4				
P4.0	44	I/O	General-purpose digital I/O, bit 0				
P4.1	45	I/O	General-purpose digital I/O, bit 1				
P4.2/STE	46	I/O	General-purpose digital I/O, slave transmit enable – USART/SPI mode				
P4.3/SIMO	47	I/O	General-purpose digital I/O, slave in/master out – USART/SPI mode				
P4.4/SOMI	48	I/O	General-purpose digital I/O, master in/slave out – USART/SPI mode				
P4.5/UCLK	49	I/O	General-purpose digital I/O, external clock input – USART				
P4.6/UTXD	50	I/O	General-purpose digital I/O, transmit data out – USART/UART mode				
P4.7/URXD	51	I/O	General-purpose digital I/O, receive data in – USART/UART mode				
R03	88	I	Input port of fourth positive (lowest) analog LCD level (V5) – LCD				
R13	89	I	Input port of third most positive analog LCD level (V3 of V4) – LCD				
R23	90	I	Input port of second most positive analog LCD level (V2) – LCD				
R33	91	0	Output of most positive analog LCD level (V1) – LCD				
RST/NMI	96	I	Reset input or non-maskable interrupt input port				
SO	57	0	Segment line S0 – LCD				
S1	58	0	Segment line S1 – LCD				
S2/O2-S5/O5	59–62	0	Segment lines S2 to S5 or digital output ports, O2-O5, group 1 – LCD				
S6/O6-S9/O9	63–66	0	Segment lines S6 to S9 or digital output ports O6-O9, group 2 – LCD				
S10/O10-S13/O13	67–70	0	Segment lines S10 to S13 or digital output ports O10-O13, group 3 – LCD				
S14/O14-S17/O17	71–74	0	Segment lines S14 to S17 or digital output ports O14-O17, group 4 – LCD				
S18/O18-S21/O21	75–78	0	Segment lines S18 to S21 or digital output ports O18-O21, group 5 – LCD				
S22/O22-S25/O25	79, 81–83	0	Segment line S22 to S25 or digital output ports O22-O25, group 6 – LCD				
S26/O26-S29/O29/CMPI	84–87	0	Segment line S26 to S29 or digital output ports O26-O29, group 7 – LCD. Segment line S29 can be used as comparator input port CMPI – Timer/Port				
ТСК	95	I	Test clock. TCK is the clock input port for device programming and test.				
TDI/VPP	93	I	Test data input. TDI/VPP is used as a data input port or input for programming voltage.

detailed description

processing unit

The processing unit is based on a consistent and orthogonal designed CPU and instruction set. This design structure results in a RISC-like architecture, highly transparent to the application development, which is distinguished by ease of programming. All operations other than program-flow instructions consequently are performed as register operations in conjunction with seven addressing modes for source and four modes for destination operand.

CPU registers

The CPU has sixteen registers that provide reduced instruction execution time. This reduces the register-to-register operation execution time to one cycle of the processor frequency.

Four of the registers are reserved for special use as a program counter, a stack pointer, a status register, and a constant generator. The remaining registers are available as general-purpose registers.

Peripherals are connected to the CPU using a data address and control bus and can be handled easily with all instructions for memory manipulation.

SLAS227A – OCTOBER 1999 – REVISED JUNE 2000

detailed description (continued)

instruction set

The instruction set for this register-register architecture provides a powerful and easy-to-use assembly language. The instruction set consists of 51 instructions with three formats and seven addressing modes. Table 1 provides a summation and example of the three types of instruction formats; the address modes are listed in Table 2.

Table 1.	Instruction	Word	Formats
----------	-------------	------	---------

Dual operands, source-destination	e.g. ADD R4,R5	$R4 + R5 \rightarrow R5$
Single operands, destination only	e.g. CALL R8	$PC \rightarrow (TOS), R8 \rightarrow PC$
Relative jump, un-/conditional	e.g. JNE	Jump-on equal bit = 0

Instructions that can operate on both word and byte data are differentiated by the suffix .B when a byte operation is required.

Examples:

Instruction	s for word operation:
MOV	EDE,TONI
ADD	#235h,&MEM
PUSH	R5
SWPB	R5

Instructions for byte operation:MOV.BEDE,TONIADD.B#35h,&MEMPUSH.BR5

Table 2. Address Mode Descriptions

ADDRESS MODE	S	D	SYNTAX	EXAMPLE	OPERATION
Register $\sqrt{\sqrt{-1}}$ N		MOV Rs,Rd	MOV Rs,Rd MOV R10,R11		
Indexed		\checkmark	MOV X(Rn),Y(Rm)	MOV 2(R5),6(R6)	$M(2+R5) \rightarrow M(6+R6)$
Symbolic (PC relative)		√	MOV EDE,TONI		$M(EDE) \rightarrow M(TONI)$
Absolute		\checkmark	MOV &MEM,&TCDAT		$M(MEM) \rightarrow M(TCDAT)$
Indirect			MOV @Rn,Y(Rm)	MOV @R10,Tab(R6)	$M(R10) \rightarrow M(Tab+R6)$
Indirect autoincrement	\checkmark		MOV @Rn+,Rm	MOV @R10+,R11	$ \begin{array}{c} M(R10) \rightarrow R11 \\ R10 + 2 \rightarrow R10 \end{array} $
Immediate			MOV #X,TONI	MOV #45,TONI	#45 \rightarrow M(TONI)

NOTE 1: S = source, D = destination.

Computed branches (BR) and subroutine calls (CALL) instructions use the same address modes as the other instructions. These addressing modes provide *indirect* addressing, ideally suited for computed branches and calls. The full use of this programming capability permits a program structure different from conventional 8- and 16-bit controllers. For example, numerous routines can easily be designed to deal with pointers and stacks instead of using flag type programs for flow control.

operation modes and interrupts

The MSP430 operating modes support various advanced requirements for ultralow-power and ultralow-energy consumption. This is achieved by the intelligent management of the operations during the different module operation modes and CPU states. The requirements are fully supported during interrupt event handling. An interrupt event awakens the system from each of the various operating modes and returns with the RETI instruction to the mode that was selected before the interrupt event. The clocks used are ACLK and MCLK. ACLK is the crystal frequency and MCLK, a multiple of ACLK, is used as the system clock.

The following five operating modes are supported:

- Active mode (AM). The CPU is enabled with different combinations of active peripheral modules.
- Low-power mode 0 (LPM0). The CPU is disabled, peripheral operation continues, ACLK and MCLK signals are active, and loop control for MCLK is active.
- Low-power mode 1 (LPM1). The CPU is disabled, peripheral operation continues, ACLK and MCLK signals are active, and loop control for MCLK is inactive.
- Low-power mode 2 (LPM2). The CPU is disabled, peripheral operation continues, ACLK signal is active, and MCLK and loop control for MCLK are inactive.
- Low-power mode 3 (LPM3). The CPU is disabled, peripheral operation continues, ACLK signal is active, MCLK and loop control for MCLK are inactive, and the dc generator for the digital controlled oscillator (DCO) (→MCLK generator) is switched off.
- Low-power mode 4 (LPM4). The CPU is disabled, peripheral operation continues, ACLK signal is inactive (crystal oscillator stopped), MCLK and loop control for MCLK are inactive, and the dc generator for the DCO is switched off.

The special function registers (SFR) include module-enable bits that stop or enable the operation of the specific peripheral module. All registers of the peripherals may be accessed if the operational function is stopped or enabled, however, some peripheral current-saving functions are accessed through the state of local register bits. An example is the enable/disable of the analog voltage generator in the LCD peripheral, which is turned on or off using one register bit.

The most general bits that influence current consumption and support fast turnon from low power operating modes are located in the status register (SR). Four of these bits control the CPU and the system clock generator: SCG1, SCG0, OscOff, and CPUOff.

interrupts

Software determines the activation of interrupts through the monitoring of hardware set interrupt flag status bits, the control of specific interrupt enable bits in SRs, the establishment of interrupt vectors, and the programming of interrupt handlers. The interrupt vectors and the power-up starting address are located in ROM address locations 0FFFFh through 0FFE0h. Each vector contains the 16-bit address of the appropriate interrupt handler instruction sequence. Table 3 provides a summation of interrupt functions and addresses.

SLAS227A – OCTOBER 1999 – REVISED JUNE 2000

operation modes and interrupts (continued)

INTERRUPT SOURCE	INTERRUPT FLAG	SYSTEM INTERRUPT	WORD ADDRESS	PRIORITY

Table 3. Interrupt Functions and Addresses

NOTES: 2. Multiple source flags

3. Interrupt flags are located in the individual module registers.

4. Non-maskable : neither the individual or the general interrupt enable bit will disable an interrupt event.

5. (Non)-maskable: the individual interrupt enable bit can disable an interrupt event, but the general interrupt enable bit cannot.

special function registers

Most interrupt and module enable bits are collected into the lowest address space. Special function register bits that are not allocated to a functional purpose are not physically present in the device. Simple software access is provided with this arrangement.

SLAS227A - OCTOBER 1999 - REVISED JUNE 2000

ROM memory organization

peripherals

Peripherals that are connected to the CPU through a data, address, and controls bus can be handled easily with instructions for memory manipulation.

oscillator and system clock

Two clocks are used in the system: the system (master) clock (MCLK) and the auxiliary clock (ACLK). The MCLK is a multiple of the ACLK. The ACLK runs with the crystal oscillator frequency. The special design of the oscillator supports the feature of low current consumption and the use of a 32 768 Hz crystal. The crystal is connected across two terminals without any other external components required.

The oscillator starts after applying VCC, due to a reset of the control bit (OscOff) in the status register (SR). It can be stopped by setting the OscOff bit to a 1. The enabled clock signals ACLK, ACLK/2, ACLK/4, or MCLK are accessible for use by external devices at output terminal XBUF.

The controller system clocks have to deal with different requirements according to the application and system condition. Requirements include:

- High frequency in order to react quickly to system hardware requests or events
- Low frequency in order to minimize current consumption, EMI, etc.
- Stable frequency for timer applications e.g., real-time clock (RTC)
- Enable start-stop operation with minimum delay to operation function

These requirements cannot all be met with fast frequency high-Q crystals or with RC-type low-Q oscillators. This compromise and selected for the MSP430, uses a low-crystal frequency, which is multiplied to achieve the desired nominal operating range:

 $f_{(system)} = (N + 1) \times f_{(crystal)}$

SLAS227A - OCTOBER 1999 - REVISED JUNE 2000

oscillator and system clock (continued)

The crystal frequency multiplication is achieved with a frequency locked loop (FLL) technique. The factor N is set to 31 after a power-up clear condition. The FLL technique, in combination with a digital controlled oscillator (DCO), provides immediate start-up capability together with long term crystal stability. The frequency variation of the DCO with the FLL inactive is typically 330 ppm, which means that with a cycle time of 1 μ s the maximum possible variation is 0.33 ns. For more precise timing, the FLL can be used, which forces longer cycle times if the previous cycle time was shorter than the selected one. This switching of cycle times makes it possible to meet the chosen system frequency over a long period of time.

The start-up operation of the system clock depends on the previous machine state. During a PUC, the DCO is reset to its lowest possible frequency. The control logic starts operation immediately after recognition of PUC.

multiplication

The multiplication operation is supported by a dedicated peripheral module. The module performs 16x16, 16x8, 8x16, and 8x8 bit operations. The module is capable of supporting signed and unsigned multiplication as well as signed and unsigned multiply and accumulate operations. The result of an operation can be accessed immediately after the operands have been loaded into the peripheral registers. No additional clock cycles are required.

digital I/O

Five eight-bit I/O ports (P0 thru P4) are implemented. Port P0 has six control registers, P1 and P2 have seven control registers, and P3 and P4 modules have four control registers to give maximum flexibility of digital input/output to the application:

- Individual I/O bits are independently programmable.
- Any combination of input, output, and interrupt conditions is possible.
- Interrupt processing of external events is fully implemented for all eight bits of the P0, P1, and P2 ports.
- Read/write access is available to all registers by all instructions.

The seven registers are:

- Input register contains information at the pins
- Output register contains output information
- Direction register controls direction
- Interrupt edge select contains input signal change necessary for interrupt
- Interrupt flags indicates if interrupt(s) are pending
- Interrupt enable contains interrupt enable pins
- Function select determines if pin(s) used by module or port

These registers contain eight bits each with the exception of the interrupt flag register and the interrupt enable register which are 6 bits each. The two least significant bit (LSBs) of the interrupt flag and enable registers are located in the special function register (SFR). Five interrupt vectors are implemented, one for Port P0.0, one for Port P0.1, one commonly used for any interrupt event on Port P0.2 to Port P0.7, one commonly used for any interrupt event on Port P1.0 to Port P1.7, and one commonly used for any interrupt event on Port P2.0 to Port P2.7.

SLAS227A - OCTOBER 1999 - REVISED JUNE 2000

LCD drive

The liquid crystal displays (LCDs) for static, 2-, 3-, and 4-MUX operation can be driven directly. The operation of the controller LCD logic is defined by software through memory-bit manipulation. The LCD memory is part of the LCD module, not part of data memory. Eight mode and control bits define the operation and current consumption of the LCD drive. The information for the individual digits can be easily obtained using table programming techniques combined with the proper addressing mode. The segment information is stored into LCD memory using instructions for memory manipulation.

The drive capability is defined by the external resistor divider that supports analog levels for 2-, 3-, and 4-MUX operation. Groups of the LCD segment lines can be selected for digital output signals. The MSP430x33x configuration has four common lines, 30 segment lines, and four terminals for adjusting the analog levels.

Basic Timer1

The Basic Timer1 (BT1) divides the frequency of MCLK or ACLK, as selected with the SSEL bit, to provide low-frequency control signals. This is done within the system by one central divider, the Basic Timer1, to support low current applications. The BTCTL control register contains the flags which control or select the different operational functions. When the supply voltage is applied or when a reset of the device (RST/NMI pin), a watchdog overflow, or a watchdog security key violation occurs, all bits in the register hold undefined or unchanged status. The user software usually configures the operational conditions on the BT during initialization.

The Basic Timer1 has two eight bit timers which can be cascaded to a sixteen bit timer. Both timers can be read and written by software. Two bits in the SFR address range handle the system control interaction according to the function implemented in the Basic Timer1. These two bits are the Basic Timer1 interrupt flag (BTIFG) and the Basic Timer1 interrupt enable (BTIE) bit.

Watchdog Timer

The primary function of the Watchdog Timer (WDT) module is to perform a controlled system restart after a software upset has occurred. If the selected time interval expires, a system reset is generated. If this watchdog function is not needed in an application, the module can work as an interval timer, which generates an interrupt after the selected time interval.

The Watchdog Timer counter (WDTCNT) is a 15/16-bit upcounter which is not directly accessible by software. The WDTCNT is controlled using the Watchdog Timer control register (WDTCTL), which is an 8-bit read/write register. Writing to WDTCTL, in both operating modes (watchdog or timer) is only possible by using the correct password in the high-byte. The low-byte stores data written to the WDTCTL. The high-byte password is 05Ah. If any value other than 05Ah is written to the high-byte of the WDTCTL, a system reset PUC is generated. When the password is read its value is 069h. This minimizes accidental write operations to the WDTCTL register. In addition to the Watchdog Timer control bits, there are two bits included in the WDTCTL that configure the NMI pin.

USART

The universal synchronous/asynchronous interface is a dedicated peripheral module which provides serial communications. The USART supports synchronous SPI (3 or 4 pin) and asynchronous UART communications protocols, using double buffered transmit and receive channels. Data streams of 7 or 8 bits in length can be transferred at a rate determined by the program, or by a rate defined by an external clock. Low-power applications are optimized by UART mode options which allow for the receipt of only the first byte of a complete frame. The applications software then decides if the succeeding data is to be processed. This option reduces power consumption.

Two dedicated interrupt vectors are assigned to the USART module, one for the receive and one for the transmit channel.

Timer/Port

The Timer/Port module has two 8-Bit Timer/Counters, an input that triggers one counter, and six digital outputs with 3-state capability. Both counters have an independent clock selector for selecting an external signal or one of the internal clocks (ACLK or MCLK). One of the counters has an extended control capability to halt, count continuously, or gate the counter by selecting one of two external signals. This gate signal sets the interrupt flag if an external signal is selected and the gate stops the counter.

Both timers can be read to and written from by software. The two 8-Bit Timer/Counters can be cascaded to form a 16-bit counter. A common interrupt vector is implemented. The interrupt flag can be set by three events in the 8-Bit Timer/Counter mode (gate signal or overflow from the counters) or by two events in the 16-bit counter mode (gate signal or overflow from the cascaded counter).

slope A/D conversion

Slope A/D conversion is accomplished with the Timer/Port module using external resistor(s) for reference (R_{ref}), using external resistor(s) to the measured (R_{meas}), and an external capacitor. The external components are driven by software in such a way that the internal counter measures the time that is needed to charge or discharge the capacitor. The reference resistor's (R_{ref}) charge or discharge time is represented by N_{ref} counts. The unknown resistors (R_{meas}) charge or discharge time is represented by N_{meas} counts. The unknown resistor's value R_{meas} is the value of R_{ref} multiplied by the relative number of counts (N_{meas}/N_{ref}). This value determines resistive sensor values that correspond to the physical data, for example temperature, when an NTC or PTC resistor is used.

Timer_A

The Timer_A module (see Figure1) offers one sixteen bit counter and five capture/compare registers. The timer clock source can be selected to come from an external source TACLK (SSEL=0), the ACLK (SSEL=1), or MCLK (SSEL=2 or SSEL=3). The clock source can be divided by one, two, four, or eight. The timer can be fully controlled (in word mode) since it can be halted, read, and written. It can be stopped or run continuously. It can count up or count up/down using one compare block to determine the period. The five capture/compare blocks are configured by the application software to run in either capture or compare mode.

The capture mode is primarily used to measure external or internal events with any combination of positive, negative, or both edges of the clock. The clock can also be stopped in capture mode by software. One external event (CCISx=0) per capture block can be selected. If CCISx=1, the ACLK is the capture signal; and if CCISx=2 or CCISx=3, software capture is chosen.

The compare mode is primarily used to generate timing for the software or application hardware or to generate pulse-width modulated output signals for various purposes like D/A conversion functions or motor control. An individual output module, which can run independently of the compare function or is triggered in several ways, is assigned to each of the five capture/compare registers.

Two interrupt vectors are used by the Timer_A module. One individual vector is assigned to capture/compare block CCR0 and one common interrupt vector is assigned to the timer and the other four capture/compare blocks. The five interrupt events using the common vector are identified by an individual interrupt vector word. The interrupt vector word is used to add an offset to the program counter to continue the interrupt handler software at the correct location. This simplifies the interrupt handler and gives each interrupt event the same interrupt handler overhead of 5 cycles.

SLAS227A - OCTOBER 1999 - REVISED JUNE 2000

Timer_A (continued)

Figure 1. Timer_A, MSP430x337 Configuration

8-Bit Timer/Counter

The 8-bit interval timer supports three major functions for applications:

- Serial communication or data exchange
- Plus counting or plus accumulation
- Timer

The 8-Bit Timer/Counter peripheral includes the following major blocks: an 8-bit up-counter with preload register, an 8-bit control register, an input clock selector, an edge detection (e.g. start bit detection for asynchronous protocols), and an input and output data latch, triggered by the carry-out-signal from the 8-Bit Timer/Counter.

The 8-Bit Timer/Counter counts up with an input clock, which is selected by two control bits from the control register. The four possible clock sources are MCLK, ACLK, the external signal from terminal P0.1, and the signal from the logical AND of MCLK and terminal P0.1.

Two counter inputs (load, enable) control the counter operation. The load input controls load operations. A write-access to the counter results in loading the content of the preload register into the counter. The software writes or reads the preload register with all instructions. The preload register acts as a buffer and can be written immediately after the load of the counter is completed. The enable input enables the count operation. When the enable signal is set to high, the counter will count-up each time a positive clock edge is applied to the clock input of the counter.

SLAS227A - OCTOBER 1999 - REVISED JUNE 2000

absolute maximum ratings[†]

Supply voltage range, between: V _{CC} terminals	
V _{SS} terminals	0.3 V to 0.3 V
Input voltage range to any VSS terminal: V _{CC1}	−0.3 V to 6 V
V _{CC2}	−0.3 V to 6 V
Input voltage range to any terminal (referenced to VSS)	–0.3 V to V _{CC} + 0.3 V
Diode current at any device terminal	±2 mA
Storage temperature range, T _{stg} : Unprogrammed device	−55°C to 150°C
Programmed device	−40°C to 85°C

† Stresses beyond those listed under "absolute maximum ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated under "recommended operating conditions" is not implied. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability. NOTE: All voltages referenced to VSS.

NOTES: A. Ground potential for all port output drivers and input terminals, excluding first inverter/buffer

B. Ground potential for entire device core logic and peripheral modules

Figure 2. Supply Voltage Interconnection

t(H) or t(L)			5 V	300		^f (system)	115
^f (XBUF)		XBUF, $C_L = 20 \text{ pF}$	3 V/5 V			f(system)	
^f (TAx)	Output frequency	TA0-4, C _L = 20 pF	3 V/5 V	DC		f _(system) /2	MHz
f(UCLK)		UCLK, $C_L = 20 \text{ pF}$	3 V/5 V	DC		^f (system)	
^t (Xdc)		XBUF, $C_L = 20 \text{ pF}$ f(MCLK)= 1.1 MHz f(XBUF) = f(ACLK) f(XBUF) = f(ACLK/n)	3 V/5 V 3 V/5 V 3 V/5 V	40% 35%	50	60% 65%	
Δt (TA)	Duty cycle of output	TA04, $C_L = 20 \text{ pF}$ t(TAH) = t(TAL)	3 V/5 V		0	±100	ns
∆t(UC)		UCLK, $C_{(L)} = 15pF$ t(UCH) = t(UCL)	3 V/5 V		0	±100	ns
$t(\tau)$	USART: Deglitch time	See Note16	3 V 5 V	0.6 0.3		2.6 1.4	μs

NOTES: 13. The external signal sets the interrupt flag every time $t_{(int)}$ is met. It may be set even with trigger signals shorter than $t_{(int)}$. The conditions to set the flag must be met independently from this timing constraint. $T_{(int)}$ is defined in MCLK cycles.

14. The external interrupt signal cannot exceed the maximum input frequency (f(in))

15. The external capture signal triggers the capture event every time t_(cap) is met. It may be triggered even with capture signals shorter than t_(cap). The conditions to set the flag must be met independently from this timing constraint.

16. The signal applied to the USART receive signal/terminal (URXD) should meet the timing requirements of $t_{(T)}$ to ensure that the URXS flip-flop is set. The URXS flip-flop is set with negative pulses meeting the minimum timing condition of $t_{(T)}$. The operating conditions to set the flag must be met independently from this timing constraint. The deglitch circuitry is active only on negative transitions on the URXD line.

typical input/output schematics (continued)

LCD OUTPUT (COM0-4, Sn, Sn/On)

NOTE A: The signals VA, VB, VC, and VD come from the LCD module analog voltage generator.

SLAS227A - OCTOBER 1999 - REVISED JUNE 2000

- NOTES: A. During programming activity and when blowing the JTAG enable fuse, the TDI/VPP terminal is used to apply the correct voltage source. The TDO/TDI terminal is used to apply the test input data for JTAG circuitry.
 - B. The TDI/VPP terminal of the 'P337A and 'E337A does not have an internal pullup resistor. An external pulldown resistor is recommended to avoid a floating node, which could increase the current consumption of the device. *Remove the external pulldown resistors when switching from P/E337A to C337 devices. Otherwise system power consumption will increase.*
 - C. The TDO/TDI terminal is in a high-impedance state after POR. The 'P337A and 'E337A need a pullup or a pulldown resistor to avoid floating a node, which could increase the current consumption of the device.
 - D. The pullup resister is only implemented in C-version

Figure 6. MSP430P/E337A: TDI/VPP, TDO/TDI

SLAS227A - OCTOBER 1999 - REVISED JUNE 2000

typical input/output schematics (continued)

NOTES: A. Optional selection of pullup or pulldown resistors available on ROM (masked) versions. B. Fuses for the optional pullup and pulldown resistors can only be programmed at the factory.

JTAG fuse check mode

MSP430 devices that have the fuse on the TDI/VPP terminal have a fuse check mode that tests the continuity of the fuse the first time the JTAG port is accessed after a power-on reset (POR). When activated, a fuse check current, I_{TF} , of 1 mA at 3 V, 2.5 mA at 5 V can flow from the TDI/VPP pin to ground if the fuse is not burned. Care must be taken to avoid accidentally activating the fuse check mode and increasing overall system power consumption.

Activation of the fuse check mode occurs with the first negative edge on the TMS pin after power up or if the TMS is being held low during power up. The second positive edge on the TMS pin deactivates the fuse check mode. After deactivation, the fuse check mode remains inactive until another POR occurs. After each POR the fuse check mode has the potential to be activated.

Fuse check current may or may not flow continuously while the fuse check mode is active, depending on which type of device is in use and the state of the TMS pin.

For the mask ROM or C versions, the fuse check current will only flow when the fuse check mode is active and the TMS pin is in a low state (see Figure 20). Therefore, the additional current flow can be prevented by holding the TMS pin high (default condition).

Figure 20. Fuse Check Mode Current, MSP430C33x

For the OTP or P versions, the fuse check current will flow continuously when fuse check mode is active, regardless of the state of the TMS pin, until the fuse check mode is deactivated with the second positive edge at the TMS pin (see Figure 21).

Figure 21. Fuse Check Mode Current, MSP430P337A

Care must be taken to avoid accidentally activating the fuse check mode, including guarding against EMI/ESD spikes that could cause signal edges on the TMS pin.
