H8S/2338 Series, H8S/2328 Series

Overview

HITACHI

ADE-802-223 Rev. 1.0 09/09/98 Hitachi, Ltd. MC-Setsu

Cautions

- 1. Hitachi neither warrants nor grants licenses of any rights of Hitachi's or any third party's patent, copyright, trademark, or other intellectual property rights for information contained in this document. Hitachi bears no responsibility for problems that may arise with third party's rights, including intellectual property rights, in connection with use of the information contained in this document.
- 2. Products and product specifications may be subject to change without notice. Confirm that you have received the latest product standards or specifications before final design, purchase or use.
- 3. Hitachi makes every attempt to ensure that its products are of high quality and reliability. However, contact Hitachi's sales office before using the product in an application that demands especially high quality and reliability or where its failure or malfunction may directly threaten human life or cause risk of bodily injury, such as aerospace, aeronautics, nuclear power, combustion control, transportation, traffic, safety equipment or medical equipment for life support.
- 4. Design your application so that the product is used within the ranges guaranteed by Hitachi particularly for maximum rating, operating supply voltage range, heat radiation characteristics, installation conditions and other characteristics. Hitachi bears no responsibility for failure or damage when used beyond the guaranteed ranges. Even within the guaranteed ranges, consider normally foreseeable failure rates or failure modes in semiconductor devices and employ systemic measures such as fail-safes, so that the equipment incorporating Hitachi product does not cause bodily injury, fire or other consequential damage due to operation of the Hitachi product.
- 5. This product is not designed to be radiation resistant.
- 6. No one is permitted to reproduce or duplicate, in any form, the whole or part of this document without written approval from Hitachi.
- 7. Contact Hitachi's sales office for any questions regarding this document or Hitachi semiconductor products.

Preface

Hitachi's H8S family of single-chip microcomputers comprises a number of new series offering the high performance and low power consumption of the existing H8 Series, which is widely used for machine control, etc., together with significantly greater ease of use.

The H8S/2000 Series features CPU object-level compatibility with the H8/300H Series, H8/300 Series, and H8/300L Series within the H8 Series.

Series	Features
H8S/2000	Upward-compatible with the H8/300H Series and H8/300 Series; twice the performance at the same frequency
H8/300H	16-Mbyte linear address space; upward-compatible with the H8/300 Series; concise instruction set; powerful word-size and longword-size arithmetic instructions
H8/300	64-kbyte address space; general register system; concise instruction set; powerful bit manipulation instructions
H8/300L	Same CPU as the H8/300 Series; consumer application oriented supporting modules; low voltage, low power consumption

This manual gives an overview of the 144-pin version H8S/2338 Series and 120/128-pin version H8S/2328 Series within the H8S/2000 Series.

Intended Readership: This Overview is intended for readers who have a basic understanding of microcomputers, and are looking for information on the features and functions of the H8S/2338, and H8S/2328 Series. Readers undertaking system design using these products, or requiring more detailed information on their use, should refer to the relevant Hardware Manuals, Reference Manual, and the H8S/2600 and H8S/2000 Series Programming Manual.

Section 1 Overview of H8S/2338 Series

1.1 Features of H8S/2338 Series

H8S/2338 Series microcomputers are designed for faster instruction execution, using a realtime control oriented CPU with an internal 32-bit architecture, and can run programs based on the C high-level language efficiently. As well as large-capacity ROM and RAM, these microcomputers include comprehensive on-chip supporting modules needed for control systems, simplifying the implementation of sophisticated, highperformance systems.

High-performance H8S/2000 CPU

- General-register architecture
 - Sixteen 16-bit general registers (also usable as sixteen 8-bit registers or eight 32-bit registers)
- High-speed operation suitable for realtime control
 - 20 MHz maximum operating frequency (VCC = 2.7 V to 3.6 V)
 - High-speed arithmetic operations (at 20 MHz operation)
 - 8/16/32-bit register-register add/subtract: 50 ns
 - 16×16 -bit register-register multiply: 1000 ns
 - $32 \div 16$ -bit register-register divide: 1000 ns
- Instruction set suitable for high-speed operation
 - Sixty-five types of basic instructions
 - 8/16/32-bit transfer instructions
 - Unsigned/signed multiply and divide instructions
 - Powerful bit manipulation instructions
- CPU operating mode
 - Advanced mode: Maximum 16-Mbyte address space

256-kbyte flash memory or 256-/128-kbyte mask ROM on-chip

On-chip high-speed static RAM

8 kbytes

Bus controller on-chip

- Address space divided into 8 areas, with bus specifications settable independently for each area
- Chip select output possible for areas 0 to 7
- Selection of 8-bit or 16-bit access space for each area
- 2-state or 3-state access space can be set for each area
- Number of program wait states can be set for each area
- Up to 8 Mbytes of DRAM can be directly connected (or interval timer can be used)
- External bus release function

DMA controller (DMAC)

- Selection of short address mode or full address mode
- Four channels in short address mode, two channels in full address mode
- Transfer possible in repeat mode, block transfer mode, etc.
- Single address mode transfer possible
- Can be activated by internal interrupt

Data transfer controller (DTC)

- Activated by internal interrupt or software
- Multiple transfers or multiple types of transfer possible for one activation source
- Transfer possible in repeat mode, block transfer mode, etc.
- Request can be sent to CPU for interrupt that activated DTC

16-bit timer-pulse unit (TPU)

- Six-channel 16-bit timer on-chip
- Pulse I/O processing capability for up to 16 pins
- Automatic 2-phase encoder count capability

Programmable pulse generator (PPG)

- Maximum 8-bit pulse output possible with TPU as time base
- Output trigger selectable in 4-bit groups
- Non-overlap interval can be set
- Direct output or inverse output setting possible

Two 8-bit timer (TMR) channels

Features of each channel:

- 8-bit up-counter (external event count capability)
- Two time constant registers
- 2-channel cascaded connection possible

Watchdog timer (WDT)

• Watchdog timer or interval timer function selectable

Three serial communication interface (SCI) channels (SCI0 to SCI2)

- Asynchronous mode or synchronous mode selectable
- Multiprocessor communication function
- Smart card interface function

A/D converter

- Resolution: 10 bits
- Input: 12 channels
- High-speed conversion: 6.7 µs minimum conversion time (20 MHz operation)
- Single or scan mode selectable
- Sample-and-hold function
- A/D conversion can be activated by external trigger or timer trigger

D/A converter

- Resolution: 8 bits
- Output: 4 channels

Sixteen I/O ports

• 106 I/O pins, 12 input-only pins

Interrupt controller

- Nine external interrupt pins (NMI, $\overline{IRQ0}$ to $\overline{IRQ7}$)
- 52 internal interrupt sources
- Choice of two interrupt control modes

Power-down state

- Medium-speed mode
- Sleep mode
- Module stop mode
- Software standby mode
- Hardware standby mode

Four MCU operating modes

				Exterr	nal Data Bus
Mode	CPU Operating Mode	Description	On-Chip ROM	Initial Value	Maximum Value
4	Advanced	On-chip ROM disabled expansion mode	Disabled	16 bits	16 bits
5		On-chip ROM disabled expansion mode	Disabled	8 bits	16 bits
6*		On-chip ROM enabled expansion mode	Enabled	8 bits	16 bits
7*		Single-chip mode	Enabled	_	_

Note: * Cannot be used in the H8S/2332 Series.

On-chip clock pulse generator (1:1 oscillation)

• Built-in duty correction circuit

Package

• 144-pin plastic QFP (FP-144)

Pin Functions

Туре	Symbol	I/O	Name and Function
Power	VCC	Input	Power supply
	VSS	Input	Ground
			Connected to the power supply (0 V).
Clock	XTAL	Input	Connects to a crystal oscillator.
	EXTAL	Input	Connects to a crystal oscillator, or external clock input.
	Ø	Output	System clock
Operating mode control	MD2 to MD0	Input	Set mode pins
System control	RES	Input	Reset input
	STBY	Input	Standby
	BREQ	Input	Bus request
	BREQO	Output	Bus request output
	BACK	Output	Bus request acknowledge
	FWE	Input	Flash write enable
Interrupt signal	NMI	Input	Nonmaskable interrupt
	IRQ7 to IRQ0	Input	Interrupt request 7 to 0
Address bus	A23 to A0	Output	Address bus
Data bus	D15 to D0	I/O	Data bus
Bus control	$\overline{\text{CS7}}$ to $\overline{\text{CS0}}$	Output	Chip select/low address strobe ($\overline{\text{CS7}}$ to $\overline{\text{CS0}}$)
	AS	Output	Address strobe
	RD	Output	Read
	HWR	Output	High write/write enable
	LWR	Output	Low write
	CAS	Output	Upper column address strobe/column address strobe
	LCAS	Output	Lower column address strobe
	WAIT	Input	Wait
DMA controller	DREQ1, DREQ0	Input	DMA request 1 and 0
(DMAC)	TEND1, TEND0	Output	DMA transfer end 1 and 0
	DACK1, DACK0	Output	DMA transfer acknowledge 1 and 0

Туре	Symbol	I/O	Name and Function
16-bit timer-pulse	TCLKA to TCLKD	Input	Clock input A to D
unit (TPU)	TIOCA0, TIOCB0, TIOCC0, TIOCD0	I/O	Input capture/output compare match A0 to D0
	TIOCA1, TIOCB1	I/O	Input capture/output compare match A1 and B1
	TIOCA2, TIOCB2	I/O	Input capture/output compare match A2 and B2
	TIOCA3, TIOCB3, TIOCC3, TIOCD3	I/O	Input capture/output compare match A3 to D3
	TIOCA4, TIOCB4	I/O	Input capture/output compare match A4 and B4
	TIOCA5, TIOCB5	I/O	Input capture/output compare match A5 and B5
Programmable pulse generator (PPG)	PO15 to PO0	Output	Pulse output 15 to 0
8-bit timer	TMO0, TMO1	Output	Compare match output
	TMCI0, TMCI1	Input	Counter external clock input
	TMRI0, TMRI1	Input	Counter external reset input
Watchdog timer (WDT)	WDTOVF	Output	Watchdog timer overflow
Serial communication	TxD2, TxD1, TxD0	Output	Transmit data (channel 2, 1, 0)
interface (SCI)/ Smart Card	RxD2, RxD1, RxD0	Input	Receive data (channel 2, 1, 0)
interface	SCK2, SCK1, SCK0	I/O	Serial clock (channel 2, 1, 0)
A/D converter (ADC)	AN15 to AN12, AN7 to AN0	Input	Analog input
	ADTRG	Input	A/D conversion external trigger input
D/A converter	DA3 to DA0	Output	Analog output
A/D converter and D/A converter	AVCC	Input	This is the power supply pin for the A/D converter and D/A converter.
	AVSS	Input	This is the ground pin for the A/D converter and D/A converter.
	Vref	Input	This is the reference voltage input pin for the A/D converter and D/A converter.

Internal Block Diagram of H8S/2338 Series

Section 2 Overview of H8S/2328 Series

2.1 Features of H8S/2328 Series

H8S/2328 Series microcomputers are designed for faster instruction execution, using a realtime control oriented CPU with an internal 32-bit architecture, and can run programs based on the C high-level language efficiently. As well as large-capacity ROM and RAM, these microcomputers include comprehensive on-chip supporting modules needed for control systems, simplifying the implementation of sophisticated, highperformance systems.

The H8S/2328 Series is pin-compatible with the H8S/2357 Series.

High-performance H8S/2000 CPU

- General-register architecture
 - Sixteen 16-bit general registers (also usable as sixteen 8-bit registers or eight 32-bit registers)
- High-speed operation suitable for realtime control
 - 20 MHz maximum operating frequency (VCC = 2.7 V to 3.6 V)
 - High-speed arithmetic operations (at 20 MHz operation)
 8/16/32-bit register-register add/subtract: 50 ns
 16 × 16-bit register-register multiply: 1000 ns
 32 ÷ 16-bit register-register divide: 1000 ns
- Instruction set suitable for high-speed operation
 - Sixty-five types of basic instructions
 - 8/16/32-bit transfer instructions
 - Unsigned/signed multiply and divide instructions
 - Powerful bit manipulation instructions
- CPU operating mode
 - Advanced mode: Maximum 16-Mbyte address space

256-kbyte flash memory or 256-/128-/32-kbyte mask ROM on-chip

On-chip high-speed static RAM

• 8 kbytes

Bus controller on chip

- Address space divided into 8 areas, with bus specifications settable independently for each area
- Chip select output possible for areas 0 to 7
- Selection of 8-bit or 16-bit access space for each area
- 2-state or 3-state access space can be set for each area
- Number of program wait states can be set for each area
- Up to 8 Mbytes of DRAM can be directly connected (or interval timer can be used)
- External bus release function

DMA controller (DMAC)

- Selection of short address mode or full address mode
- Four channels in short address mode, two channels in full address mode
- Transfer possible in repeat mode, block transfer mode, etc.
- Single address mode transfer possible
- Can be activated by internal interrupt

Data transfer controller (DTC)

- Activated by internal interrupt or software
- Multiple transfers or multiple types of transfer possible for one activation source
- Transfer possible in repeat mode, block transfer mode, etc.
- Request can be sent to CPU for interrupt that activated DTC

16-bit timer-pulse unit (TPU)

Internal Block Diagram of H8S/2328 Series

Section 3 CPU

3.1 Features

The H8S/2000 CPU is a high-speed central processing unit with an internal 32-bit architecture that is upward-compatible with the H8/300 and H8/300H CPUs. The H8S/2000 CPU has sixteen 16-bit general registers, can address a 16-Mbyte (architecturally 4-Gbyte) linear address space, and is ideal for realtime control.

Features

- Upward-compatible with H8/300 and H8/300H CPUs
 - Can execute H8/300 and H8/300H object programs
- General-register architecture
 - Sixteen 16-bit general registers (also usable as sixteen 8-bit registers or eight 32-bit registers)
- Sixty-five basic instructions
 - 8/16/32-bit arithmetic and logic instructions
 - Multiply and divide instructions
 - Powerful bit-manipulation instructions
- Eight addressing modes
 - Register direct [Rn]
 - Register indirect [@ERn]
 - Register indirect with displacement [@(d:16,ERn) or @(d:32,ERn)]
 - Register indirect with post-increment or pre-decrement [@ERn+ or @-ERn]
 - Absolute address [@aa:8, @aa:16, @aa:24, or @aa:32]
 - Immediate [#xx:8, #xx:16, or #xx:32]
 - Program-counter relative [@(d:8,PC) or @(d:16,PC)]
 - Memory indirect [@@aa:8]
- 16-Mbyte address space
 - Program: 16 Mbytes
 - Data: 16 Mbytes (4 Gbytes architecturally)

- High-speed operation
 - All frequently used instructions execute in one to two states
 - Maximum operating frequency: 20 MHz
 - 8/16/32-bit register-register add/subtract: 50 ns
 - -- 8 × 8-bit register-register multiply: 600 ns
 - $-16 \div 8$ -bit register-register divide: 600 ns
 - 16 \times 16-bit register-register multiply: 1000 ns
 - $-32 \div 16$ -bit register-register divide: 1000 ns
- CPU operating mode
 - Advanced mode
- Power-down state
 - Transition to power-down state by SLEEP instruction
 - CPU operating clock can be selected

Differences between H8S/2600 CPU and H8S/2000 CPU: The differences between the H8S/2600 CPU and the H8S/2000 CPU are as shown below.

• Register configuration

The MAC register is supported only by the H8S/2600 CPU.

• Basic instructions

The four instructions MAC, CLRMAC, LDMAC, and STMAC are supported only by the H8S/2600 CPU.

• Number of execution states

The number of execution states of the MULXU and MULXS instructions.

In addition, there are differences in address space, EXR register function, power-down modes, etc., depending on the model. Refer to the hardware manual for the relevant product for details.

Differences from H8/300 CPU: In comparison to the H8/300 CPU, the H8S/2000 CPU has the following enhancements.

- More general registers and control registers
 - Eight 16-bit expanded registers, and one 8-bit control register, have been added.
- Address space
 - The 16-Mbyte address space can be used effectively

- Enhanced instructions
 - Addressing modes of bit-manipulation instructions have been enhanced.
 - Signed multiply and divide instructions have been added.
 - Two-bit shift instructions have been added.
 - Instructions for saving and restoring multiple registers have been added.
 - A test and set instruction has been added.
- Higher speed
 - Basic instructions execute twice as fast.

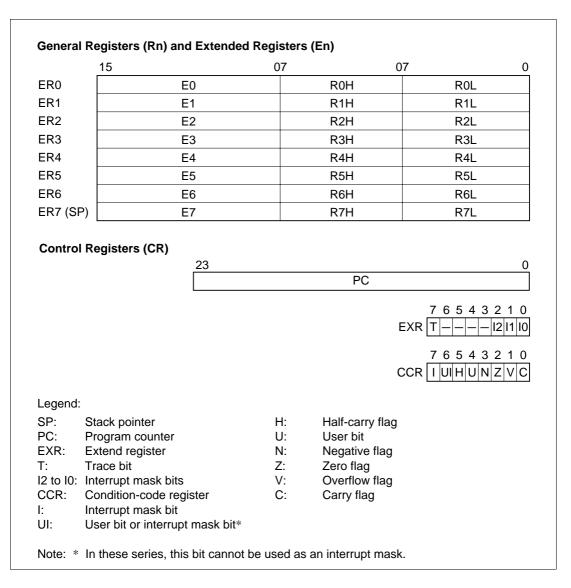

Differences from H8/300H CPU: In comparison to the H8/300H CPU, the H8S/2000 CPU has the following enhancements.

- Additional control register
 - One 8-bit control register has been added.
- Enhanced instructions
 - Addressing modes of bit-manipulation instructions have been enhanced.
 - Two-bit shift instructions have been added.
 - Instructions for saving and restoring multiple registers have been added.
 - A test and set instruction has been added.
- Higher speed
 - Basic instructions execute twice as fast.

3.2 Register Configuration

The H8S/2000 CPU has general registers and control registers. The eight 32-bit general registers all have identical functions and can be used as either address registers or data registers. The control registers are the 24-bit program counter (PC), 8-bit extended register (EXR), and 8-bit condition code register (CCR).

CPU Internal Registers

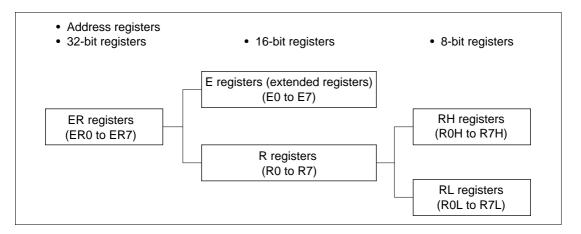

General Registers: The CPU has eight 32-bit general registers. These general registers are all functionally alike and can be used as both address registers and data registers. When a general register is used as a data register, it can be accessed as a 32-bit, 16-bit, or 8-bit register. When the general registers are used as 32-bit registers or address registers, they are designated by the letters ER (ER0 to ER7).

The ER registers divide into 16-bit general registers designated by the letters E (E0 to E7) and R (R0 to R7). These registers are functionally equivalent, providing a maximum sixteen 16-bit registers. The E registers (E0 to E7) are also referred to as extended registers.

The R registers divide into 8-bit general registers designated by the letters RH (R0H to R7H) and RL (R0L to R7L). These registers are functionally equivalent, providing a maximum sixteen 8-bit registers.

The figure below illustrates the usage of the general registers. The usage of each register can be selected independently.

Usage of General Registers

Control Registers: The control registers are the 24-bit program counter (PC), 8-bit extend register (EXR), and 8-bit condition-code register (CCR).

• Program Counter (PC)

This 24-bit counter indicates the address of the next instruction the CPU will execute. The length of all CPU instructions is 2 bytes (one word), so the least significant PC bit is ignored. (When an instruction code is read, the least significant bit is regarded as 0.)

• Extend Register (EXR)

This 8-bit register comprises a trace bit (T) and interrupt mask bits (I2 to I0).

— Bit 7—Trace Bit (T)

Specifies whether or not trace mode is set. When this bit is cleared to 0, instructions are executed sequentially. When set to 1, trace exception handling is started each time an instruction is executed.

- Bits 6 to 3-Reserved
- Bits 2 to 0-Interrupt Mask Bits (I2 to I0)

These bits specify the interrupt request mask level (0 to 7). See section 3.9, Interrupts, for details.

EXR can be manipulated by the LDC, STC, ANDC, ORC, and XORC instructions. Except in the case of STC, interrupts (including NMI) are not accepted for 3 states after the instruction is executed.

• Condition-Code Register (CCR)

This 8-bit register contains internal CPU status information, including an interrupt mask bit (I) and half-carry (H), negative (N), zero (Z), overflow (V), and carry (C) flags.

- Bit 7-Interrupt Mask Bit (I)

Masks interrupts other than NMI when set to 1. (NMI is accepted regardless of the I bit setting.) The I bit is set to 1 when exception handling execution is started. For details, refer to section 3.9, Interrupts.

- Bit 6-User Bit or Interrupt Mask Bit (UI)

Can be written and read by software using the LDC, STC, ANDC, ORC, and XORC instructions. In these series, this bit cannot be used as an interrupt mask.

- Bit 5-Half-Carry Flag (H)

When the ADD.B, ADDX.B, SUB.B, SUBX.B, CMP.B, or NEG.B instruction is executed, this flag is set to 1 if there is a carry or borrow at bit 3, and cleared to 0 otherwise. When the ADD.W, SUB.W, CMP.W, or NEG.W instruction is executed, the H flag is set to 1 if there is a carry or borrow at bit 11, and cleared to 0 otherwise. When the ADD.L, SUB.L, CMP.L, or NEG.L instruction is executed, the H flag is set to 1 if there is a carry or borrow at bit 27, and cleared to 0 otherwise.

- Bit 4-User Bit (U)

Can be written and read by software using the LDC, STC, ANDC, ORC, and XORC instructions.

— Bit 3—Negative Flag (N)

Stores the value of the most significant bit (sign bit) of data.

- Bit 2-Zero Flag (Z)

Set to 1 to indicate zero data, and cleared to 0 to indicate non-zero data.

- Bit 1-Overflow Flag (V)

Set to 1 when an arithmetic overflow occurs, and cleared to 0 at other times.

— Bit 0—Carry Flag (C)

Set to 1 when a carry occurs, and cleared to 0 otherwise. Used by:

- Add instructions, to indicate a carry
- Subtract instructions, to indicate a borrow
- Shift and rotate instructions, to store the carry

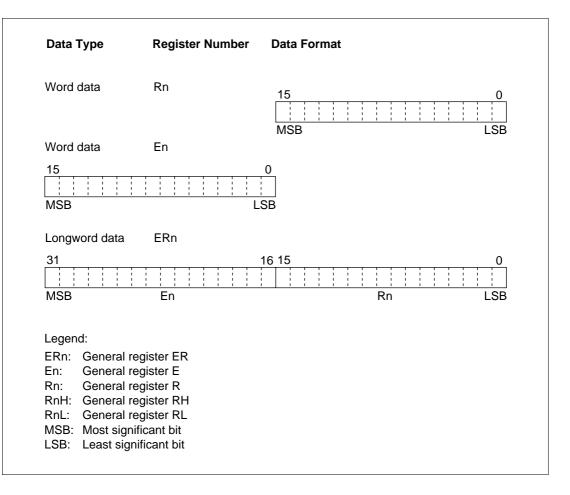

The carry flag is also used as a bit accumulator by bit manipulation instructions.

3.3 Data Formats

The CPU can process 1-bit, 4-bit (BCD), 8-bit (byte), 16-bit (word), and 32-bit (longword) data. Bit-manipulation instructions operate on 1-bit data by accessing bit n (n = 0, 1, 2, ..., 7) of byte operand data. The DAA and DAS decimal-adjust instructions treat byte data as two digits of 4-bit BCD data.

Data Type	Register Number	Data Format
1-bit data	RnH	7 0 7 6 5 4 3 2 1 0 Don't care
1-bit data	RnL	7 0 Don't care 7 6 5 4 3 2 1 0
4-bit BCD data	RnH	7 4 3 0 Upper Lower Don't care
4-bit BCD data	RnL	7430Don't careUpperLower
Byte data	RnH	7 0 Don't care MSB LSB
Byte data	RnL	7 0 Don't care MSB LSB

General Register Data Formats (cont)

Memory Data Formats

Data Type		Data Format							
	Address				-	_			
		7							0
1-bit data	Address L	7	6	5	4	3	2	1	0
Byte data	Address L	MSB		1 	1 	1 	1 	1 	LSB

	Address 2N + 1			1 1 1	1	1 1 1	1	1 1 1	1
	Address 2N + 2			 	1	 	1	 	
	Address 2N + 3								LSB
					_	/			

3.4 Addressing Modes

The H8S/2000 CPU supports eight addressing modes.

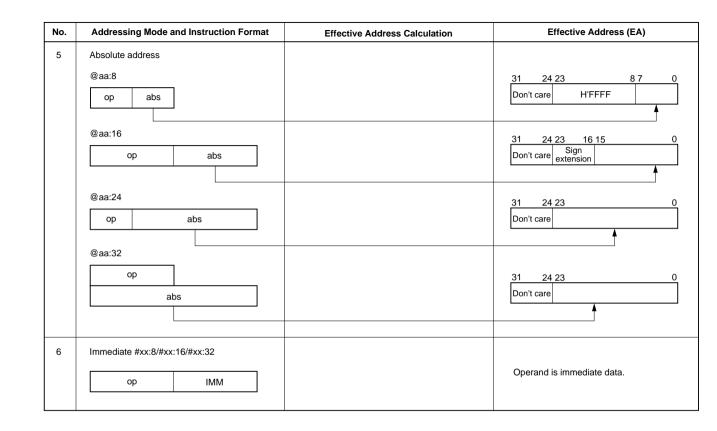

Addressing Modes

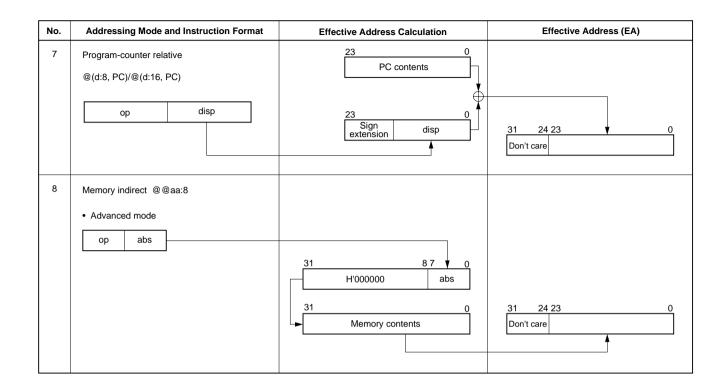

No.	Addressing Mode	Symbol
1	Register direct	Rn
2	Register indirect	@ERn
3	Register indirect with displacement	@(d:16,ERn)/@(d:32,ERn)
4	Register indirect with post-increment Register indirect with pre-decrement	@ERn+ @–ERn
5	Absolute address	@aa:8/@aa:16/@aa:24/@aa:32
6	Immediate	#xx:8/#xx:16/#xx:32
7	Program-counter relative	@(d:8,PC)/@(d:16,PC)
8	Memory indirect	@@aa:8

Effective Address Calculation

0 C C C Operand is general register contents. Effective Address (EA) 24 23 23 23 23 24 24 24 Don't care Don't care Don't care Don't care ž š č ž æ ►⊕ 0 c С 0 1, 2, or 4 1, 2, or 4 Effective Address Calculation General register contents General register contents General register contents disp General register contents Value Added or Subtracted 2 ~ 4 Sign extension Operand Size Longword Word Byte 3 33 õ 33 3 ٨ ٨ Register indirect with pre-decrement @-ERn Register indirect with post-increment @ERn+ Addressing Mode and Instruction Format Register indirect with post-increment or Register indirect with displacement @ (d:16, ERn) or @(d:32, ERn) disp Register indirect (@ERn) E Register direct (Rn) E pre-decrement -d do do do do ° N . 2 ო 4

The upper 8 bits of the effective address are ignored, giving a 16-bit address.

3.5 Instruction Set

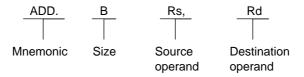

The H8S/2000 CPU has 65 types of instructions.

Features

- Upward-compatible at object level with H8/300H and H8/300 CPUs
- General register architecture
- 8/16/32-bit transfer instructions and arithmetic and logic instructions
 - Byte (B), word (W), and longword (L) formats for transfer instructions and basic arithmetic and logic instructions
- Unsigned and signed multiply and divide instructions
- Powerful bit manipulation instructions
- Instructions for saving and restoring multiple registers

Assembler Format

The ADD instruction format is shown below as an example.

• Data transfer Instructions

Notes: *1: The number of states is the number of states required for execution when the instruction code and operands are located in on-chip memory.

*2: n is the initial value of R4L or R4.

[1] 7 states when the number of restored/saved registers is 2, 9 states when 3, and 11 states when 4.

[2] Cannot be used with the H8S/2000 CPU.

[3] Set to 1 when there is a carry from or borrow to bit 11; otherwise cleared to 0.

[4] Set to 1 when there is a carry from or borrow to bit 27; otherwise cleared to 0.

[5] If the result is zero, the previous value of the flag is retained; otherwise the flag is cleared to 0.

[6] Set to 1 if the divisor is negative: otherwise cleared to 0.

[7] Set to 1 if the divisor is zero; otherwise cleared to 0.

[8] Set to 1 if the quotient is negative; otherwise cleared to 0.

[9] When EXR is valid, the number of states is increased by 1.

Number of States Required for Execution

The number of states shown in the instruction set table is the number of states required for execution when the op code and operand data are located in a one-cycle area on which word access is possible, such as on-chip memory. When the op code or operand data is accessed from an on-chip supporting module or an external address, the number of states increases as shown in the table below.

....

			Acc	ess Condi	tions		
					Extern	al Device	
			n-Chip ting Module	8-B	it Bus	16-E	Bit Bus
Execution State (Cycle)	On-Chip Memory	8-Bit Bus	16-Bit Bus	2-State Access	3-State Access	2-State Access	3-State Access
Instruction fetch	1	4	2	4	6 + 2m	2	3 + m
Branch instruction read	_						
Stack operation	_						
Byte data access	_	2		2	3 + m	-	
Word data access		4		4	6 + 2m	-	
Internal operation	1	1	1	1	1	1	1

• Number of States Required for Execution (Cycle)

Legend

m: Number of wait states inserted in external device access

Condition Code Notation

Symbol	Meaning
\$	Changes according operation result.
*	Indeterminate (value not guaranteed).
0	Always cleared to 0.
1	Always set to 1.
_	Not affected by operation result.

Operation Notation

Rd	General register (destination)*
Rs	General register (source)*
Rn	General register*
ERn	General register (32-bit register)
(EAd)	Destination operand
(EAs)	Source operand
EXR	Extend register
CCR	Condition-code register
Ν	N (negative) flag in CCR
Z	Z (zero) flag in CCR
V	V (overflow) flag in CCR
С	C (carry) flag in CCR
PC	Program counter
SP	Stack pointer
#IMM	Immediate data
disp	Displacement
+	Addition
-	Subtraction
×	Multiplication
÷	Division
^	Logical AND
V	Logical OR
\oplus	Logical exclusive OR
\rightarrow	Transfer from left-hand operand to right-hand operand, or transition from left- hand state to right-hand state
٦	NOT (logical complement)
() < >	Operand contents
:8/:16/:24/:32	8-, 16-, 24-, or 32-bit length

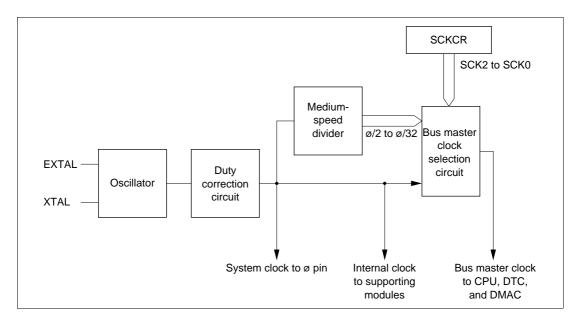

Note: * General registers include 8-bit registers (R0H to R7H, R0L to R7L), 16-bit registers (R0 to R7, E0 to E7), and 32-bit registers (ER0 to ER7).

3.6 Basic Bus Timing

The CPU operates on the basis of the ø clock. One ø clock cycle is called a state. The bus cycle consists of one, two, or three states. Different access methods are used for on-chip memory, on-chip supporting modules, and the external address space.

Basic Clock Timing

An external clock is input to the EXTAL pin, or a crystal oscillator is connected to the EXTAL pin, to generate the system clock (\emptyset). An external clock or crystal oscillator of the same frequency as the \emptyset clock should be used.

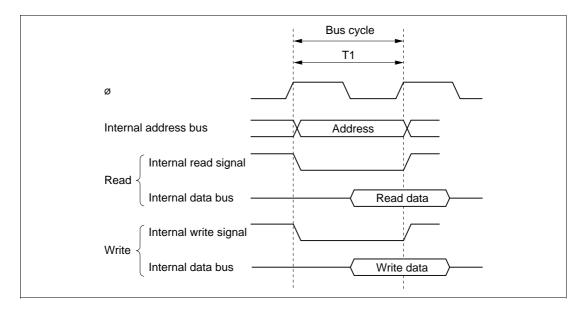

CPU Read/Write Cycles

The CPU operates on the basis of the ø clock. One ø clock cycle is called a state, and a bus cycle consists of one, two, or three states. Different access methods are used for on-chip memory, on-chip supporting modules, and external address space. Access to the external address space can be controlled by the bus controller.

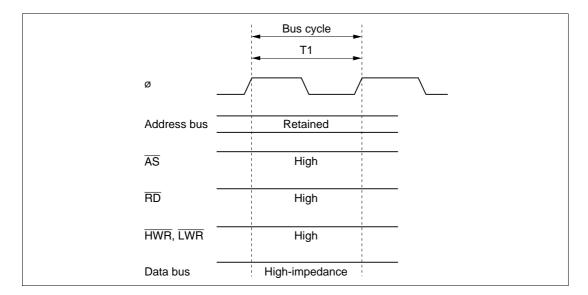

On-Chip Memory

On-chip memory is accessed in one state. The data bus is 16 bits wide, permitting both byte and word access.

• On-Chip Memory Access Cycle (One-state Access)

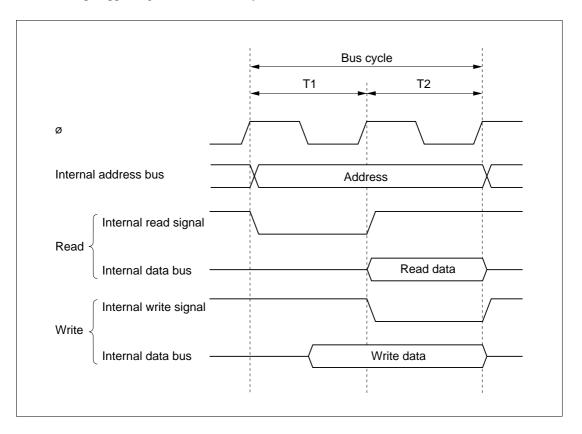

• Pin States during On-Chip Memory Access

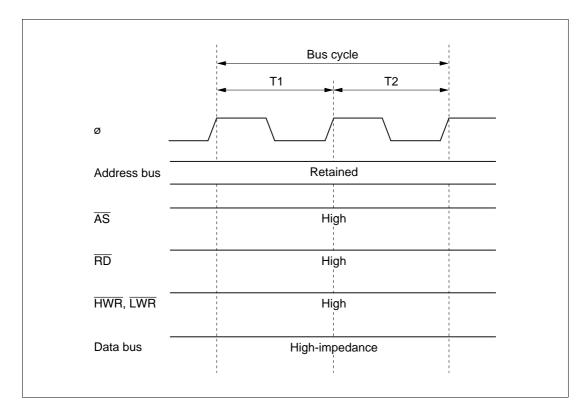

On-Chip Supporting Modules

The on-chip supporting modules are accessed in two states. The data bus is either 8 bits or 16 bits wide, depending on the internal I/O register.

• On-Chip Supporting Module Access Cycle (Two-state Access)

• Pin States during On-Chip Supporting Module Access

External Address Space

The external address space is accessed with an 8-bit or 16-bit data bus width in a two-state or three-state bus cycle. In three-state access, wait states can be inserted. For further details, refer to section 4.1, Bus Controller (BSC).

3.7 Processing States

The H8S/2000 CPU has five processing states: the reset state, program execution state, exception-handling state, bus-released state, and power-down state.

Reset State: State in which the CPU and all on-chip supporting modules are initialized and halted.

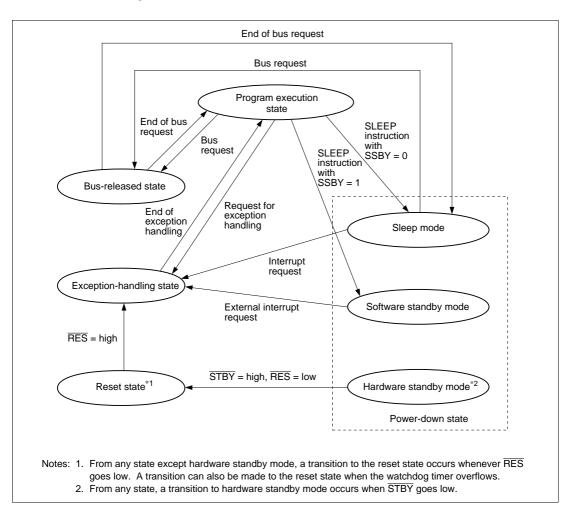

Program Execution State: State in which the CPU executes the program sequentially.

Exception-Handling State: Transient state in which the normal processing flow is altered and exception handling executed as the result of a reset, interrupt, or trap instruction exception handling source.

Bus-Released State: State in which the external bus is released in response to a bus request signal from a bus master other than the CPU.

Power-Down State: State in which CPU operation is stopped, and power consumption is kept low (sleep mode, software standby mode, hardware standby mode). The power-down state also includes medium-speed mode and module stop mode.

State Transition Diagram

3.8 Exception Handling

H8S/2000 CPU exception handling is activated by a reset, a trap instruction, or an interrupt. A priority system is provided for exception handling, and simultaneously generated exceptions are handled in order of priority.

Priority	Exception Type	Start of Exception Handling
High ▲	Reset	Starts immediately after a low-to-high transition at the $\overline{\text{RES}}$ pin, or when the watchdog timer overflows.
	Trace	Starts when execution of the current instruction or exception handling ends, if the trace (T) bit is set to 1
	Interrupt	Starts when execution of the current instruction or exception handling ends, if an interrupt request has been issued
Low	Trap instruction (TRAPA)	Started by execution of a trap instruction (TRAPA)

Exception Types and Priority

Exception Handling Operation

Exception handling is initiated by various exception handling sources. Trap instruction exception handling is always accepted in the program execution state. Trap instructions and interrupts are handled as follows:

- 1. The program counter (PC), condition code register (CCR), and extend register (EXR) are pushed onto the stack.
- 2. The interrupt mask bits are updated. The T bit is cleared to 0.
- 3. A vector address corresponding to the activation source is generated, and program execution starts from the address indicated in that vector address.

For a reset exception, steps 2 and 3 above are carried out.

Exception Vector Table

Exception Source	Exception Source		Vector Address*1
Reset		0	H'0000 to H'0003

	IRQ7	23	H'005C to H'005F
Internal interrupt*2		24	H'0060 to H'0063
-		to	
		91	H'015C to H'015F

Notes: 1. Lower 16 bits of the address.

2. For details of internal interrupt vectors, see section 3.9, Interrupts.

3.9 Interrupts

Interrupts are controlled by the interrupt controller. There are a total of 61 interrupt sources, comprising nine external interrupts from the external pins (NMI, $\overline{IRQ0}$ to $\overline{IRQ7}$), and 52 internal interrupts from on-chip supporting modules. A separate vector number is assigned to each interrupt.

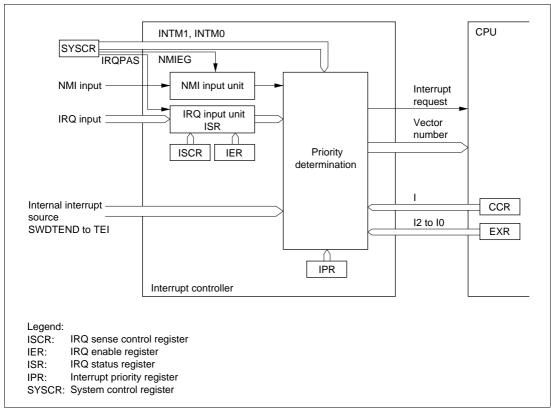

Interrupt Control

Either of two interrupt control modes can be set by means of the INTM1 and INTM0 bits in the system control register (SYSCR).

The interrupt controller controls interrupts on the basis of the control mode set by the INTM1 and INTM0 bits, the interrupt priorities set by interrupt priority register (IPR), and the masking conditions set by the I bit in CCR and bits I2 to I0 in EXR.

NMI is the highest-priority interrupt, and is always accepted.

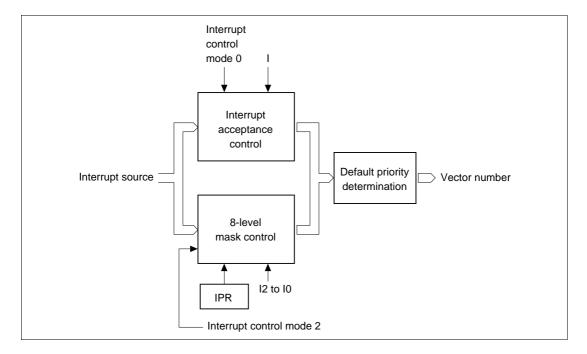

Block Diagram of Interrupt Controller

Interrupt Control Modes

Interrupt	SY	SCR	Priority Setting	Interrupt	
Control Mode	INTM1	INTM0	Registers	Mask Bits	Description
0	0	0	_	I	Interrupt mask control is performed by the I bit.
_	_	1	—	_	Setting prohibited
2	1	0	IPR	l2 to l0	8-level interrupt mask control is performed by bits I2 to I0. 8 priority levels can be set with IPR.
_	_	1	_	—	Setting prohibited

Block Diagram of Interrupt Control Operation

Interrupt Control Mode 0: Enabling and disabling of IRQ interrupts and on-chip supporting module interrupts can be set by means of the I bit in CCR. Interrupts are enabled when the I bit is cleared to 0, and disabled when set to 1.

Interrupt Control Mode 2: Eight-level masking can be implemented for IRQ interrupts and onchip supporting module interrupts by comparing the interrupt mask level bits (I2 to I0) in EXR and the IPR priority level.

Interrupt Sources, Vector Addresses, and Interrupt Priorities

Interrupt Source	Origin of Interrupt Source	Vector Number	Vector Address*	IPR	Priority
NMI	External	7	H'001C		High

3.10 Operating Modes

In these series, there are two operating modes for the ROMless versions, four for the mask ROM versions, and eight for the F-ZTAT versions. These modes allow the selection of initial settings for the CPU operating mode, enabling/disabling of on-chip ROM, and the bus width, by setting the mode pins (MD2 to MD0).

Operating Mode	Mask ROM Versions	F-ZTAT Versions	ROMIess Versions
4		\checkmark	\checkmark
5		\checkmark	
6			—
7		\checkmark	—
10	—	\checkmark	—
11	—		—
14	—	\checkmark	—
15	—	\checkmark	—

Operating Modes for Each ROM Type

Note: Modes 0 to 3, 8, 9, 12, and 13 are not supported, and must not be set.

Mode 4 (On-Chip ROM Disabled Expanded Mode): The CPU can access a 16-Mbyte address space in advanced mode. The on-chip ROM is disabled. Ports A, B and C function as an address bus, ports D and E function as a data bus, and part of port F carries bus control signals.

The initial bus mode after a reset is 16 bits, with 16-bit access to all areas. However, if 8-bit access is designated by the bus controller for all areas, the bus mode switches to 8 bits.

Mode 5 (On-Chip ROM Disabled Expanded Mode): The CPU can access a 16-Mbyte address space in advanced mode. The on-chip ROM is disabled. Pins P13 to P10 and ports A, B and C function as an address bus, port D functions as a data bus, and part of port F carries bus control signals.

The initial bus mode after a reset is 8 bits, with 8-bit access to all areas. However, if at least one area is designated for 16-bit access by the bus controller, the bus mode switches to 16 bits and port E becomes a data bus.

Mode 6 (On-Chip ROM Enabled Expanded Mode): The CPU can access a 16-Mbyte address space in advanced mode. The on-chip ROM is enabled. Pins P13 to P10 and ports A, B and C function as input ports immediately after a reset. These pins can be set to output addresses by setting the corresponding bits to 1 in the pin function control register (PFCR) in the case of pins P13 to P10 and ports A and B, or in the data direction register (DDR) for port C. Port D functions as a data bus, and part of port F carries bus control signals.

The initial bus mode after a reset is 8 bits, with 8-bit access to all areas. However, if at least one area is designated for 16-bit access by the bus controller, the bus mode switches to 16 bits and port E becomes a data bus.

Mode 7 (**Single-Chip Mode**): The CPU can access a 16-Mbyte address space in advanced mode. The on-chip ROM is enabled, but external addresses cannot be accessed.

All I/O ports are available for use as input-output ports.

Mode 10 (F-ZTAT Versions Only): This is a flash memory boot mode.

Except for the fact that flash memory programming and erasing can be performed, operation in this mode is the same as in advanced on-chip ROM enabled expanded mode.

Mode 11 (F-ZTAT Versions Only): This is a flash memory boot mode.

Except for the fact that flash memory programming and erasing can be performed, operation in this mode is the same as in advanced single-chip mode.

Mode 14 (F-ZTAT Versions Only): This is a flash memory user program mode.

Except for the fact that flash memory programming and erasing can be performed, operation in this mode is the same as in advanced on-chip ROM enabled expanded mode.

Mode 15 (F-ZTAT Versions Only): This is a flash memory user program mode.

Except for the fact that flash memory programming and erasing can be performed, operation in this mode is the same as in advanced single-chip mode.

Eight MCU Operating Modes (F-ZTATTM Versions)

MCU	CPU						External Data Bus		
Operating Mode	FWE	MD2	MD1	MD0	Operating Mode	Description	On-Chip ROM	Initial Width	Max. Width

Four/Two MCU Operating Modes (Mask ROM Versions/ROMless Versions)

Note: * Only modes 4 and 5 are available in the ROMless versions (H8S/2332 and H8S/2322).

3.11 Address Maps

These series have a 16-Mbyte address space, divided into eight areas.

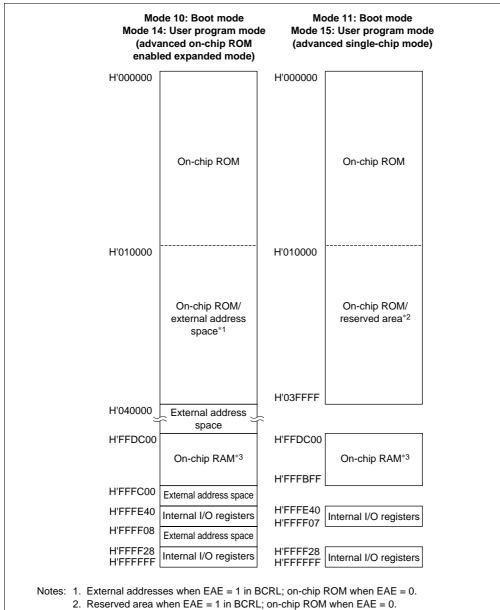

Address Maps in Each Operating Mode

Notes: 1. Only modes 4 and 5 are available in the ROMless versions (H8S/2332 and H8S/2322).

- 2. External addresses when EAE = 1 in BCRL; on-chip ROM when EAE = 0.
- 3. Reserved area when EAE = 1 in BCRL; on-chip ROM when EAE = 0.
- 4. Can be made external addresses by clearing the RAME bit to 0 in SYSCR.

Address Maps in Each Operating Mode (F-ZTAT Versions Only)

3. On-chip RAM is used for flash memory programming. Do not clear the RAME bit to 0 in SYSCR.

Section 4 Supporting Modules

4.1 Bus Controller (BSC)

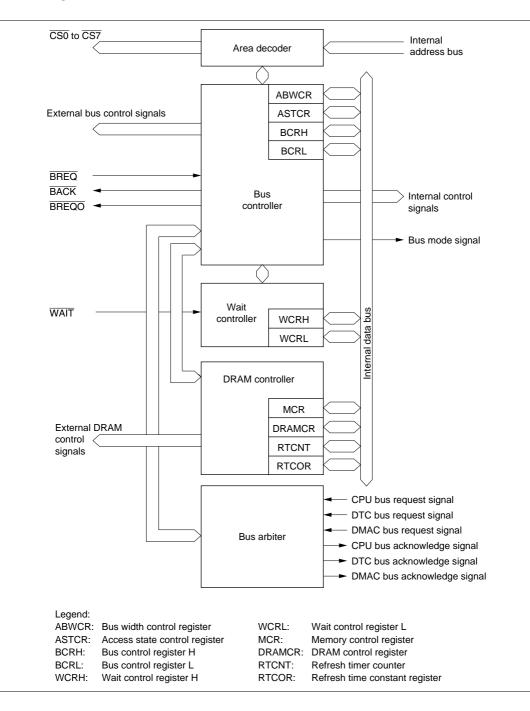

The H8S/2338 and H8S/2328 Series have a built-in bus controller (BSC) that manages the external address space divided into eight areas. The bus specifications, such as bus width and number of access states, can be set independently for each area, enabling multiple memories to be connected easily.

The bus controller also has a bus arbitration function, and controls the operation of the internal bus masters: the CPU, DMA controller (DMAC), and data transfer controller (DTC).

Features

- Manages external address space in area units
 - Manages the external space as 8 areas of 2-Mbytes
 - Bus specifications can be set independently for each area
 - DRAM/burst ROM interfaces can be set
- Basic bus interface
 - Chip select ($\overline{CS0}$ to $\overline{CS7}$) can be output for areas 0 to 7
 - 8-bit access or 16-bit access can be selected for each area
 - 2-state access or 3-state access can be selected for each area
 - Program wait states can be inserted for each area
- DRAM interface
 - DRAM interface can be set for areas 2 to 5
 - Row address/column address multiplexed output (8/9/10 bits)
 - 2-CAS method
 - Burst operation (fast page mode)
 - T_P cycle insertion to secure RAS precharging time
 - Choice of CAS-before-RAS refreshing or self-refreshing
- Burst ROM interface
 - Burst ROM interface can be set for area 0
 - Choice of 1- or 2-state burst access
- Idle cycle insertion
 - An idle cycle can be inserted in case of an external read cycle between different areas
 - An idle cycle can be inserted in case of an external write cycle immediately after an external read cycle

- Write buffer functions
 - External write cycle and internal access can be executed in parallel
 - DMA single-address mode and internal access can be executed in parallel
- Bus arbitration function
 - Includes a bus arbiter that arbitrates bus mastership among the CPU, DMAC, and DTC
- Other features
 - Refresh counter (refresh timer) can be used as an interval timer
 - External bus release function

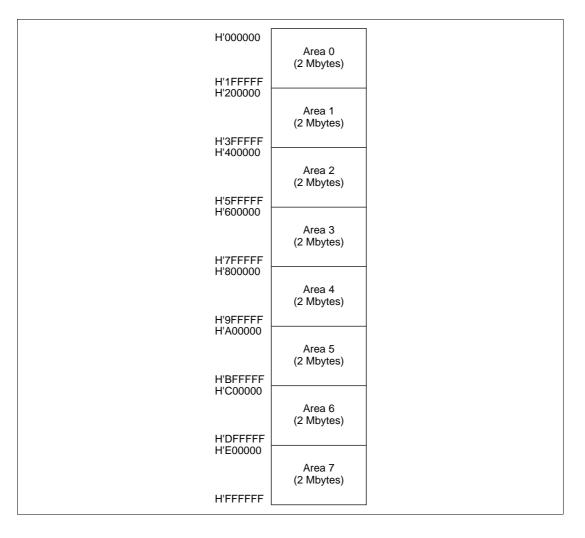

4.1.1 Area Partitioning

The bus controller partitions the 16-Mbyte address space into eight areas, 0 to 7, in 2-Mbyte units, and performs bus control for external space in area units.

Area partitioning is only effective in expanded mode, and has no significance in single-chip mode.

Overview of Area Partitioning

Bus Specifications

The external address space bus specifications consist of three elements: bus width, number of access states, and number of program wait states. The bus width and number of access states for on-chip memory and internal I/O registers are fixed , and are not affected by the bus controller.

Bus specifications can be set as shown below by means of the bus controller control registers.

ABWCR ASTCR WCRH, WCRL					Bus Specifications (Basic Bus Interface)				
ABWn	ABWn ASTn Wn1 Wn0 Bus Width		Access States	Program Wait States					
0	0	_	_	16	2	0			
	1	0	0		3	0			
			1			1			
		1	0			2			
			1			3			
1	0	_		8	2	0			
	1	0	0		3	0			
			1			1			
		1	0			2			
			1			3			

• Bus Specifications for Each Area (Basic Bus Interface)

Memory Interfaces

These series' memory interfaces comprise (1) **a basic bus interface** that allows direct connection of ROM, SRAM, and so on; (2) **a DRAM interface** that allows direct connection of DRAM; and (3) a burst ROM interface that allows direct connection of burst ROM. The interface can be designated independently for each area.

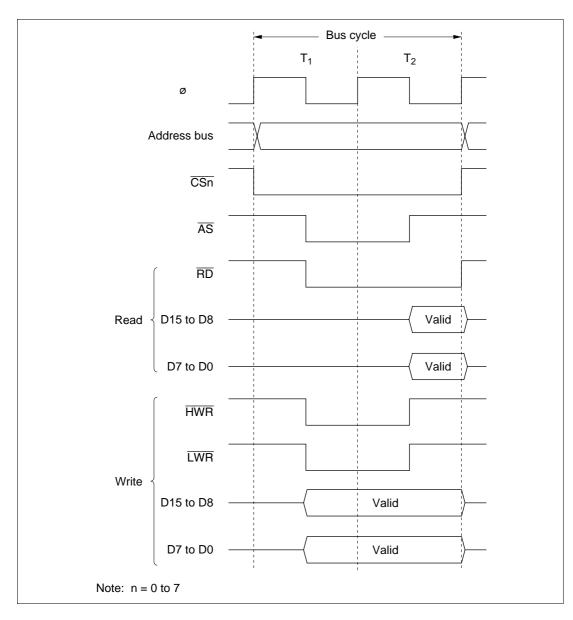

4.1.2 Basic Bus Interface

This interface can be designated for areas 0 to 7. When external space is accessed, the chip select signal ($\overline{\text{CS0}}$ to $\overline{\text{CS7}}$) for the relevant area (0 to 7) can be output.

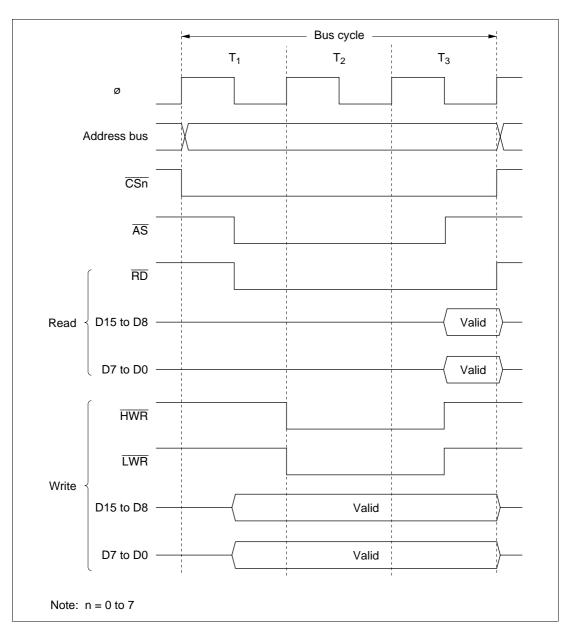

In 3-state access space, 0 to 3 program wait states or a pin wait by means of the $\overline{\text{WAIT}}$ pin can be inserted.

After a reset, all areas are designated as basic bus interface, 3-state access space (the bus width is determined by the MCU operating mode).

Basic Bus Timing (Word Access to 16-Bit 2-State Access Space)

4.1.3 DRAM Interface

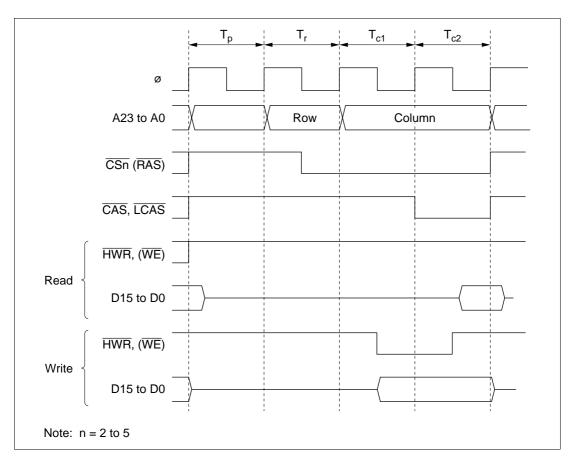

External space areas 2 to 5 can be designated as DRAM space, and DRAM interface performed. With the DRAM interface, DRAM can be directly connected to the H8S/2000 Series. Selectable DRAM space settings are: one area (area 2); two areas (areas 2 and 3); and four areas (areas 2 to 5). In an area designated as DRAM space, the $\overline{\text{CS}}$ pin functions as the $\overline{\text{RAS}}$ pin.

Features

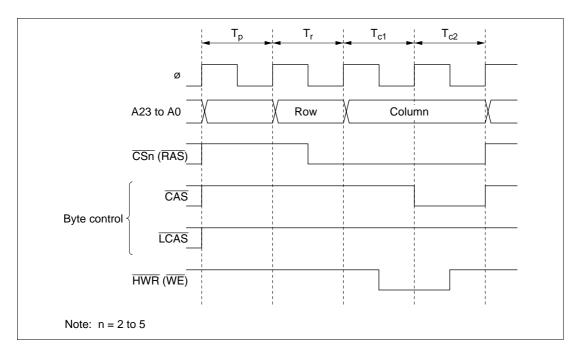

- 2/4/8-Mbyte or 128/256/512-kbyte DRAM space can be set
- Address multiplexing
 - Row address and column address are multiplexed.
 - Selection of 8, 9, or 10 bits as the row address shift size
- Basic timing
 - 4-state basic timing
 - Wait state insertion possible
- DRAM interface
 - 2-CAS system for control signals required for DRAM byte access
- Burst operation
 - Fast page mode
- Refresh control
 - Selection of CAS-before-RAS refreshing or self-refreshing
 - Can be used as interval timer

DRAM Basic Timing

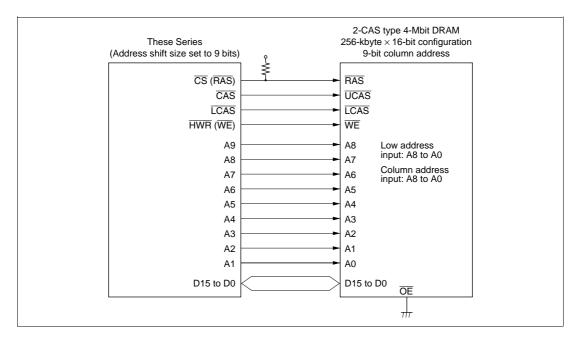

• Basic Access Timing (2-CAS System)

• Byte Access Control Timing (Upper Byte Write Access)

• Example of 2-CAS Type (LCASS = 0) Connection

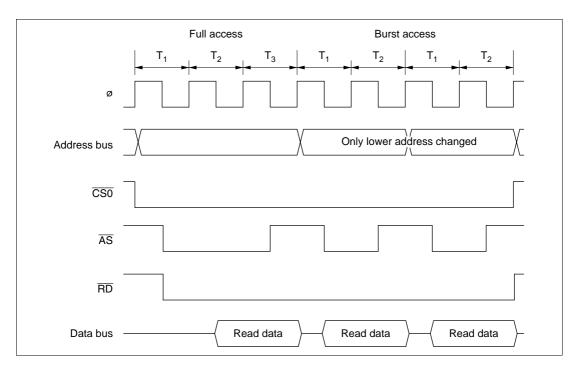

4.1.4 Burst ROM Interface

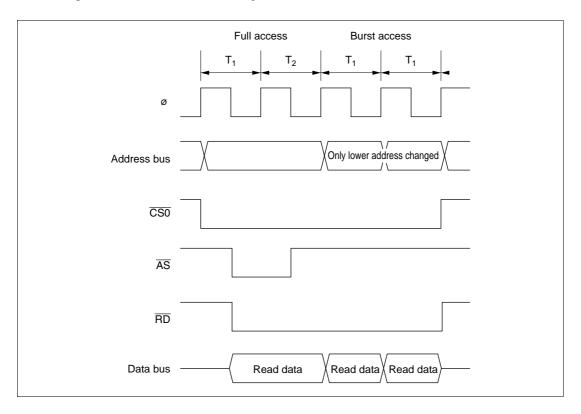

External space area 0 can be designated as burst ROM space, and burst ROM space interfacing can be performed. The burst ROM space interface enables 16-bit configuration ROM with burst access capability to be accessed at high speed.

Consecutive burst accesses of a maximum 4 words or 8 words can be performed for CPU instruction fetches only. One or two states can be selected for burst access.

• Example of Burst ROM Access Timing (When AST0 = BRSTS1 = 1)

• Example of Burst ROM Access Timing (When AST0 = BRSTS1 = 0)

4.2 DMA Controller (DMAC)

The DMA controller (DMAC) can carry out data transfer on up to 4 channels (channels 0A, 0B, 1A, and 1B). Short address transfer can be performed on each channel independently, and full address transfer is possible by using pairs of channels.

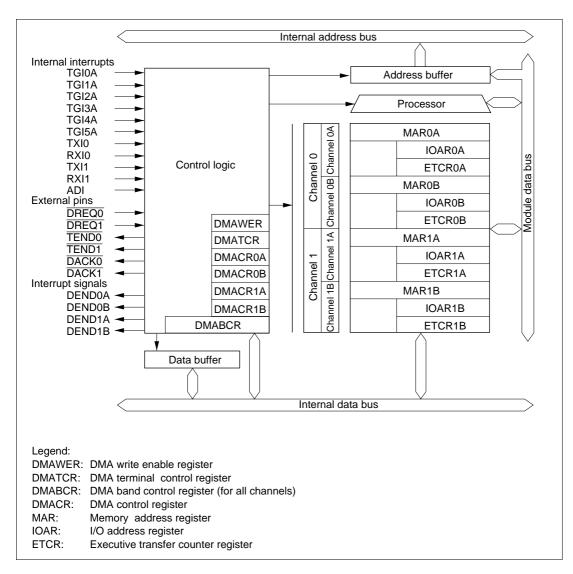

Features

- Choice of short address mode or full address mode
 - Short address mode
 - Maximum of 4 channels can be used
 - Choice of dual address mode or single address mode
 - In dual address mode, one of the two addresses, transfer source and transfer destination, is specified as 24 bits and the other as16 bits
 - In single address mode, transfer source or transfer destination address only is specified as 24 bits
 - In single address mode, transfer can be performed in one bus cycle
 - Choice of sequential mode, idle mode, or repeat mode for dual address mode and single address mode

Full address mode

- Maximum of 2 channels can be used
- Transfer source and transfer destination address specified as 24 bits
- Choice of normal mode or block transfer mode
- 16-Mbyte address space can be specified directly
- Byte or word can be set as the transfer unit
- Activation sources: internal interrupt, external request, auto-request (depending on transfer mode)
 - Six 16-bit timer-pulse unit (TPU) compare match/input capture interrupts
 - Serial communication interface (SCI) transmission complete interrupt, reception complete interrupt
 - A/D converter conversion end interrupt
 - External request
 - Auto-request
- Module stop mode can be set
 - The initial setting enables DMAC registers to be accessed. DMAC operation is halted by setting module stop mode

Block Diagram

Transfer Modes

The DMAC has the transfer modes shown in the table below. In short address mode, up to fourchannel transfer is possible, with channels A and B operating independently. In full address mode, up to two-channel transfer is possible, with channels A and B combined.

• Overview of Transfer Mode

			Address Re	gister Bit Length
Transfer	Mode	Transfer Source	Source	Destination
Short address mode	 Dual address mode Sequential mode 1-byte or 1-word transfer executed for one transfer request Memory address incremented/decremented by 1 or 2 1 to 65536 transfers Idle mode 1-byte or 1-word transfer executed for one transfer request Memory address fixed 1 to 65536 transfers Repeat mode 1-byte or 1-word transfer executed for one transfer request Memory address fixed 1 to 65536 transfers Repeat mode 1-byte or 1-word transfer executed for one transfer request Memory address fixed 1-byte or 1-word transfer executed for one transfer request After specified number of transfers (1 to 256), initial state is restored and operation continues 	 TPU channel 0 to 5 compare match/input capture A interrupt SCI transmission complete interrupt SCI reception complete interrupt A/D converter conversion end interrupt External request 	24/16	16/24
	Single address mode	External request	24/DACK	DACK/24
	 1-byte or 1-word transfer executed for one transfer request 			
	Transfer in 1 bus cycle using DACK pin in place of address specifying I/O			
	Specifiable for sequential, idle, and repeat modes

	External request — 1-byte or 1-word transfer executed for one transfer request — 1 to 65536 transfers	External rec	quest		
	 Block transfer mode Specified block size transfer executed for one transfer request 1 to 65536 transfers Either source or destination specifiable as block area Block size: 1 to 256 bytes or words 	 TPU channed to 5 comparematch/input capture A interrupt SCI transmic complete interrupt SCI reception complete interrupt SCI reception complete interrupt External reception conversion of interrupt 	ssion on quest er	24	

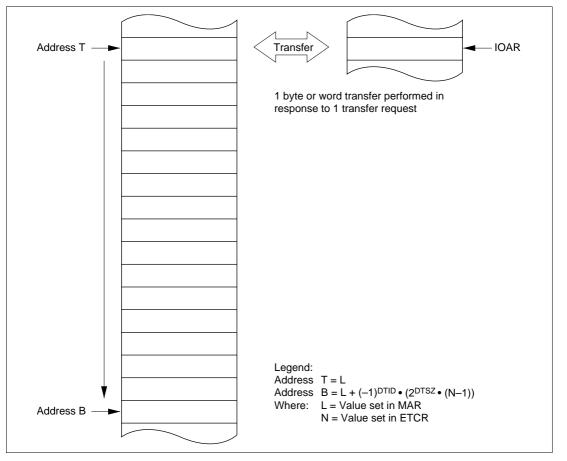

Short Address Mode

There are two kinds of short address mode—dual address mode and single address mode. Each mode incudes (1) sequential mode, (2) idle mode, (3) repeat mode, and (4) single address mode.

In short address mode, data transfer can be performed on a maximum of four channels.

(1) Sequential mode

In response to a single transfer request, the specified number of transfers are carried out, one byte or one word at a time. An interrupt request can be sent to the CPU or DTC when the specified number of transfers have been completed. One address is specified as 24 bits, and the other as 16 bits. The transfer direction is programmable.

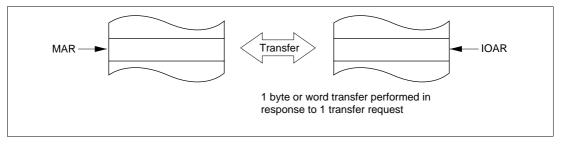

Operation in Sequential Mode

(2) Idle mode

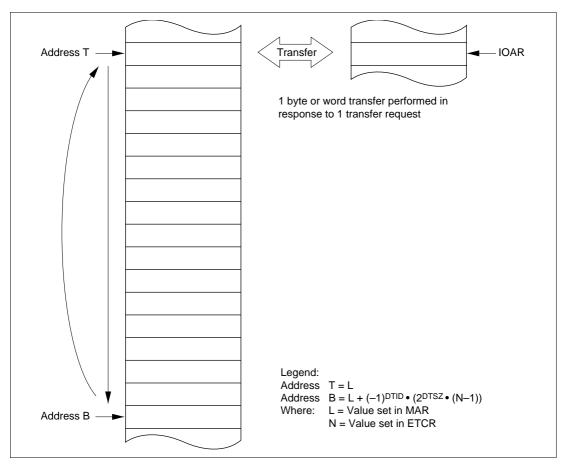

In response to a single transfer request, the specified number of transfers are carried out, one byte or one word at a time. An interrupt request can be sent to the CPU or DTC when the specified number of transfers have been completed. One address is specified as 24 bits, and the other as 16 bits. The transfer source address and transfer destination address are fixed. The transfer direction is programmable.

(3) Repeat mode

In response to a single transfer request, the specified number of transfers are carried out, one byte or one word at a time. When the specified number of transfers have been completed, the addresses and transfer counter are restored to their original settings, and operation is continued. No interrupt request is sent to the CPU or DTC. One address is specified as 24 bits, and the other as 16 bits. The transfer direction is programmable.

Operation in Idle Mode

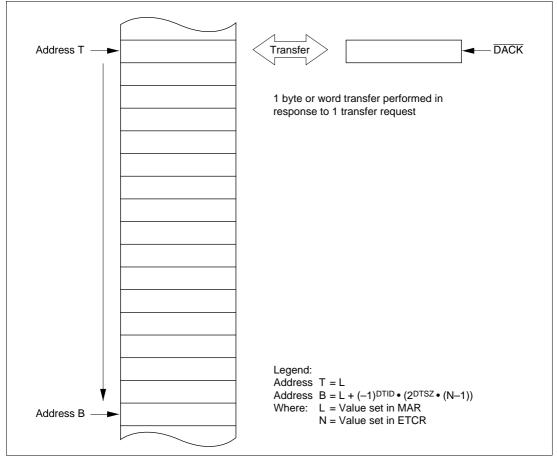

Operation in Repeat Mode

(4) Single address mode

In response to a single transfer request, the specified number of transfers are carried out between external memory and an external device, one byte or one word at a time. Unlike dual address mode, source and destination accesses are performed in parallel. Therefore, either the source or the destination is an external device which can be accessed with a strobe alone, using the \overline{DACK} pin. One address is specified as 24 bits, and for the other, the pin is set automatically. The transfer direction is programmable.

Sequential, idle, and repeat modes can also be specified for single address mode. Single address mode can only be used on channel B.

Operation in Single Address Mode (When Sequential Mode is Specified)

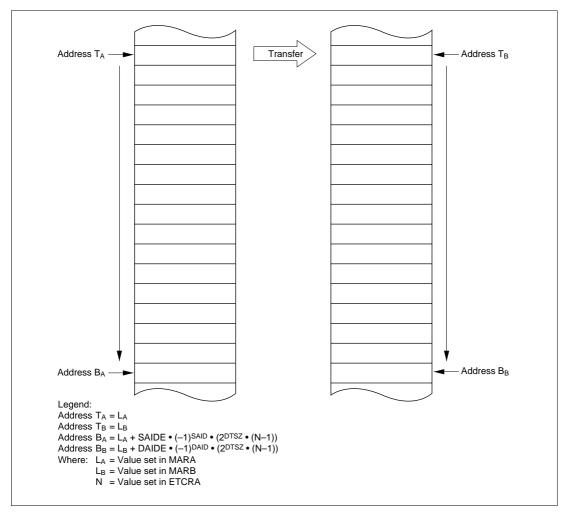

Full Address Mode

Full address mode includes (5) normal mode and (6) block transfer mode.

In full address mode, data transfer can be performed on a maximum of two channels, with channels A and B combined.

(5) Normal Mode

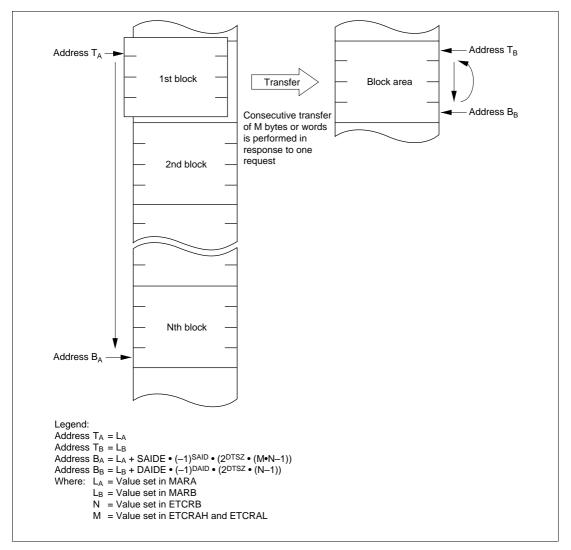

One byte or word is transferred per transfer request, and a designated number of these transfers are executed. A CPU or DTC interrupt can be requested on completion of the designated number of transfers. Both addresses are 24-bit addresses. There are two transfer requests (activation sources)—an external request and an auto request.

Operation in Normal Mode

(6) Block Transfer Mode

One block of the specified size is transfer per request, and a designated number of block transfers are executed. At the end of each block transfer, one address is restored to its initial value. When the designated number of blocks have been transferred, a CPU or DTC interrupt can be requested. Both addresses are 24-bit addresses.

Operation in Block Transfer Mode (When BLKDIR = 0: MARB is Block Area)

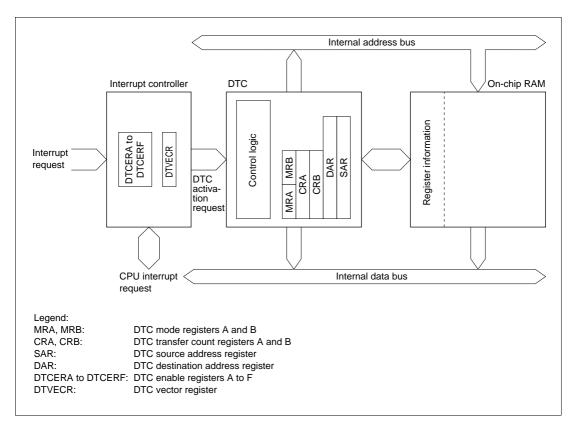

4.3 Data Transfer Controller (DTC)

The data transfer controller (DTC) is activated by an interrupt or software, and can transfer data without imposing any load on the CPU.

Features

- Transfer possible over any number of channels
 - Transfer information is stored in memory
 - One activation source can trigger a number of data transfers (chain transfer)
 - Chain transfer execution can be set after data transfer (when counter = 0)
- Variety of transfer modes
 - Normal, repeat, and block transfer modes available
 - Incrementing, decrementing, and fixing of source and destination addresses can be selected
- Direct specification of 16-Mbyte address space possible
 - 24-bit specification of transfer source and destination addresses
- Transfer can be set in byte or word units
- A CPU can be requested for the interrupt that activated the DTC
 - An interrupt request can be issued to the CPU after one data transfer ends
 - An interrupt request can be issued to the CPU after all specified data transfers have ended
- Can be activated by software
- Module stop mode can be set
 - The initial setting enables DTC registers to be accessed. DTC operation is halted by setting module stop mode.

DTC Block Diagram

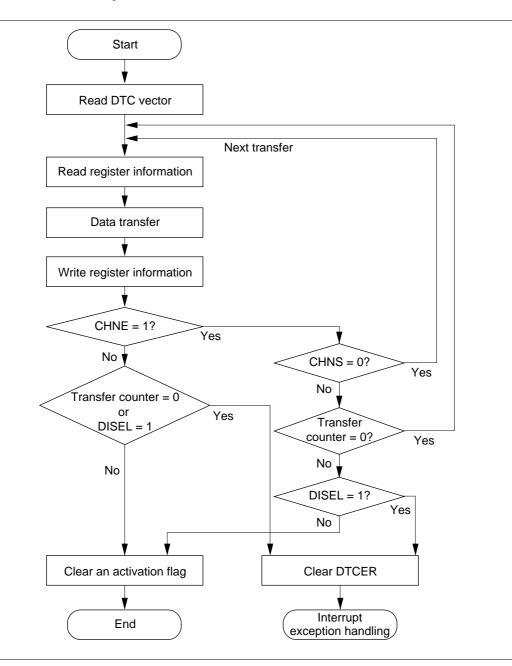

Data Transfer Operation

When a DTC activation source occurs, the DTC reads register information previously stored in memory, and transfers data on the basis of that register information. After the data transfer, it writes updated register information back to memory.

Pre-storage of register information in memory makes it possible to transfer data over any required number of channels. The DTC can also execute a number of transfers with a single activation source (chain transfer). A setting can also be made to perform chain transfer, only when the transfer counter value is 0. This enables DTC re-setting to be performed by the DTC itself.

• Flowchart of DTC Operation

• Chain Transfer Conditions

1st Transfer				2nd Transfer				
CHNE	CHNS	DISEL	CR	CHNE	CHNS	DISEL	CR	DTC Transfer
0	—	0	Nonzero	_	—	_	_	Ends with 1st transfer
0	—	0	0	—	_	_	_	Ends with 1st transfer
0	—	1	_	—	—	_	_	Interrupt request to CPU
1	0	_	_	0	_	0	Nonzero	Ends with 2nd transfer
				0	—	0	0	Ends with 2nd transfer
			_	0	—	1	_	Interrupt request to CPU
1	1	0	Nonzero	—	—	_	_	Ends with 1st transfer

								Interrupt request to CPU

DTC Activation Sources

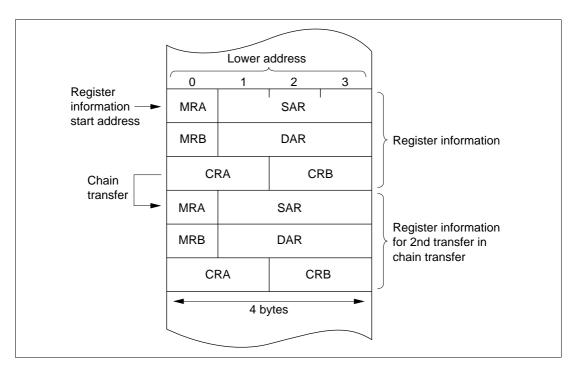

The DTC is activated by an interrupt source or by a vector number write to the DTC vector register (DTVECR) by software. An interrupt request can be designated as a CPU interrupt source or a DTC activation source.

When an interrupt has been designated a DTC activation source, existing CPU mask level and interrupt controller priorities have no effect. If there is more than one activation source at the same time, the DTC operates in accordance with the default priorities.

• Interrupt Sources and DTC Vector Address

The DTC vector address indicates the start address of the register information in memory. The MRA, SAR, MRB, DAR, CRA, and CRB registers are located in that order from the start address of the register information. Locate the register information in the on-chip RAM (addresses H'FFF800 to H'FFFBFF).

• Location of DTC Register Information in Address Space

• Interrupt Sources, DTC Vector Addresses, and Corresponding DTCEs

Interrupt Source	Origin of Interrupt Source	Vector Number	Vector Address	DTCE*	Priority
Write to DTVECR	Software	DTVECR	H'0400+ (DTVECR [6:0]<<1)	_	High

Number of DTC Execution States

Mode	Vector Read I	Register Information Read/Write J	Data Read K	Data Write L	Internal Operations M
Normal	1	6	1	1	3
Repeat	1	6	1	1	3
Block transfer	1	6	Ν	Ν	3

N: Block size (initial setting of CRA)

• Number of States Required in Each Execution State

Access To				On- Chip ROM		nal I/O isters	Exte	ernal Dev	ices	
Bus width Access states			32	16	8	16	8	8	16	16
			1	1	2	2	2	3	2	3
Execution	Vector read	SI		1	—	—	4	6+2m	2	3+m
state	Register information read/write	SJ	1	—	—	—	—	_	—	_
	Byte data read	Sĸ	1	1	2	2	2	3+m	2	3+m
	Word data read	Sĸ	1	1	4	2	4	6+2m	2	3+m
	Byte data write	S_L	1	1	2	2	2	3+m	2	3+m
	Word data write	S_L	1	1	4	2	4	6+2m	2	3+m
	Internal operation	S_{M}	1	1	1	1	1	1	1	1

Note: The number of execution states is calculated from the formula below.

Number of execution states = $I \cdot S_I + \Sigma (J \cdot S_J + K \cdot S_K + L \cdot S_L) + M \cdot S_M$

 Σ indicates the sum of all transfers activated by one activation event (the number in which the CHNE bit is set to 1, plus 1).

Transfer Modes

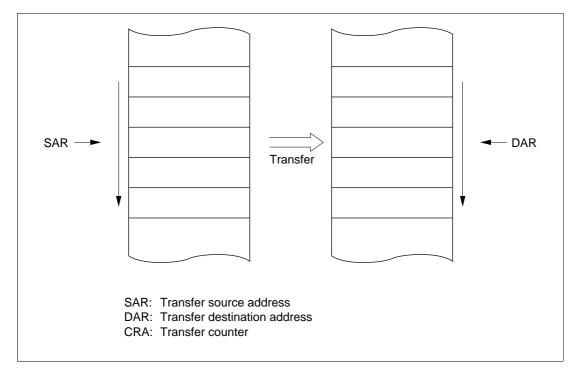

There are three DTC transfer modes—normal mode, repeat mode, and block transfer mode.

In the DTC, the 24-bit source address register (SAR) designates the transfer source address and the 24-bit destination address register (DAR) designates the transfer destination address. After each transfer, SAR and DAR are independently incremented, decremented, or left unchanged.

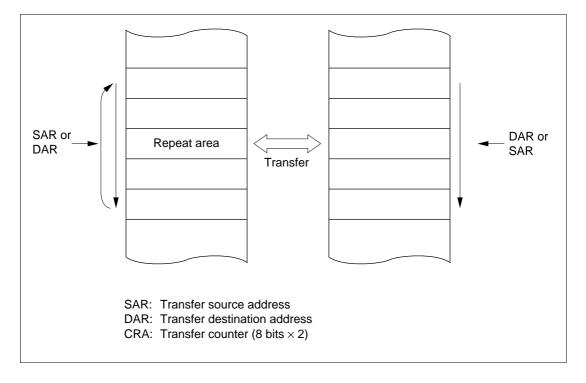

• Overview of DTC Functions

		Address Registers			
Transfer Mode	Activation Source	Transfer Source	Transfer Destination		
 Normal mode 1-byte or 1-word transfer executed for one transfer request Memory addresses are incremented or decremented by 1 or 2 Up to 65,536 transfers possible Repeat mode 1-byte or 1-word transfer executed for one transfer request Memory addresses are incremented or decremented by 1 or 2 Memory addresses are incremented or decremented by 1 or 2 Memory addresses are incremented or decremented by 1 or 2 After the specified number of transfers (1 to 256), the initial state is restored and operation continues Block transfer mode One transfer request transfers a block of the specified size Block size is from 1 to 256 bytes or words Up to 65,536 transfers possible A block area can be designated at either the source or destination 	 IRQ TPU TGI 8-bit timer CMI SCI TXI or RXI A/D converter ADI DMAC DEND Software 	24 bits	24 bits		

Operation in Normal Mode: In normal mode, one byte or one word of data is transferred in one operation. From 1 to 65,536 transfers can be specified. When the specified number of transfers have ended, a CPU interrupt can be requested.

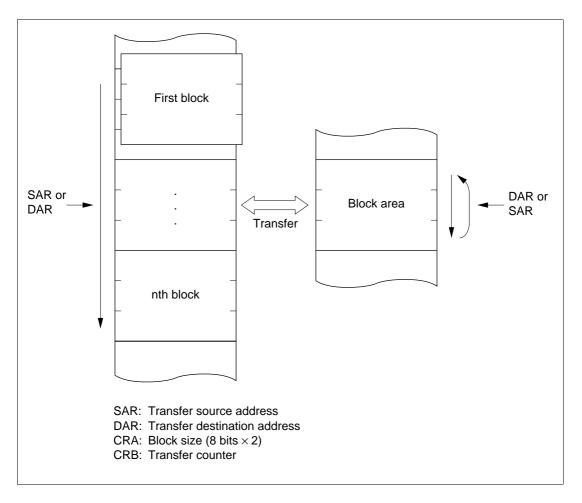

Operation in Repeat Mode: In repeat mode, one byte or one word of data is transferred in one operation. From 1 to 256 transfers can be specified. When the specified number of transfers have ended, the initial state specified in the transfer counter and repeat area is restored and transfer is repeated.

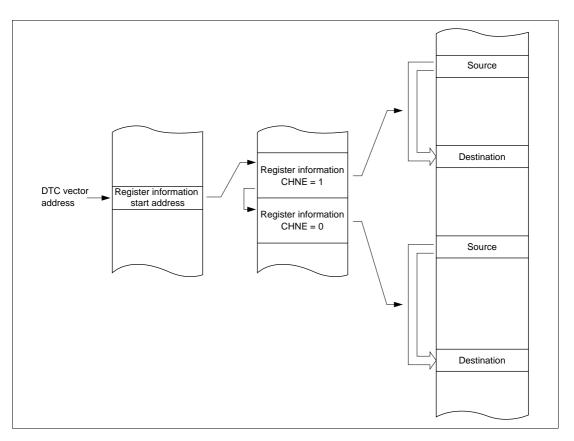

Operation in Block Transfer Mode: In block transfer mode, one operation transfers one block of data. Either the transfer source or the transfer destination is specified as a block area. The block size is 1 to 256. When the transfer of one block ends, the initial settings of the block size counter and the address register specified in the block area are restored. The other address register is continually incremented, decremented, or left unchanged.

From 1 to 65,536 transfers can be specified. When the specified number of transfers have ended, a CPU interrupt can be requested.

Chain Transfer

Setting the CHNE bit to 1 in DTC mode register B enables a number of data transfers to be performed consecutively in response to a single transfer request. Also, by setting both the CHNE bit and the CHNS bit to 1, it is possible to specify execution of chain transfer only when the transfer counter value is 0.

4.4 16-Bit Timer Pulse Unit (TPU)

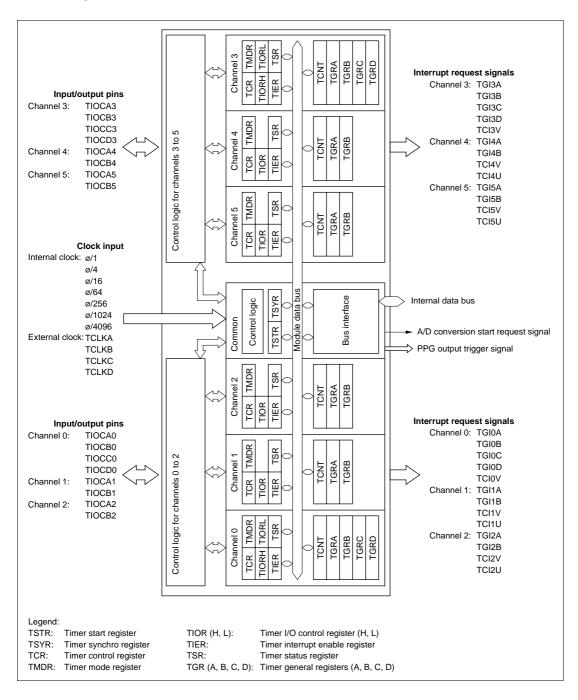

The 16-bit timer pulse unit (TPU) that comprises six 16-bit timer channels. The TPU can provide up to 16 kinds of pulse input/output.

The TPU can perform PWM output, pulse width measurement, and two-phase encoder processing, and can activate the data transfer controller (DTC) and DMA Controller (DMAC). It can also generate a programmable pulse generator (PPG) output trigger and A/D converter start trigger.

Features

- Maximum 16-pulse input/output
 - A total of 16 timer general registers (TGRs) are provided (four each for channels 0 and 3, and two each for channels 1, 2, 4, and 5), each of which can be set independently as an output compare/input capture register
- Selection of 8 counter input clocks for each channel
 - Internal clocks: ø, ø/4, ø/16, ø/64, ø/256, ø/1024, ø/4096
 - External clocks: TCLKA, TCLKB, TCLKC, TCLKD
- The following operations can be set for each channel:
 - Waveform output at compare match: Selection of 0, 1, or toggle output
 - Input capture function: Selection of rising edge, falling edge, or both edge detection
 - Counter clear operation: Counter clearing possible by compare match or input capture
 - Synchronous operation: Multiple timer counters (TCNT) can be written to simultaneously
 - Simultaneous clearing by compare match and input capture possible
 - Register simultaneous input/output possible by counter synchronous operation
 - PWM mode: Any PWM output duty can be set
 - Maximum of 15-phase PWM output possible by combination with synchronous operation
- Buffer operation settable for channels 0 and 3
 - Input capture register double-buffering possible
 - Automatic rewriting of output compare register possible
- Phase counting mode settable independently for each of channels 1, 2, 4, and 5
 - Two-phase encoder pulse up/down-count possible
- Cascaded connection operation
 - Channel 2 (channel 5) input clock operates as 32-bit counter by setting channel 1 (channel 4) overflow/underflow
- Fast access via internal 16-bit bus
 - Fast access is possible via a 16-bit bus interface

- 26 interrupt sources
 - For channels 0 and 3, four compare match/input capture dual-function interrupts and one overflow interrupt can be requested independently
 - For channels 1, 2, 4, and 5, two compare match/input capture dual-function interrupts, one overflow interrupt, and one underflow interrupt can be requested independently
- Automatic transfer of register data
 - Block transfer, 1-word data transfer, and 1-byte data transfer possible by data transfer controller (DTC) or DMA controller (DMAC) activation
- Programmable pulse generator (PPG) output trigger can be generated
 - Channel 0 to 3 compare match/input capture signals can be used as PPG output trigger
- A/D converter conversion start trigger can be generated
 - Channel 0 to 5 compare match A/input capture A signals can be used as A/D converter conversion start trigger
- Module stop mode can be set
 - As the initial setting, TPU operation is halted. Register access is enabled by exiting module stop mode.

Interrupt Sources and Data Transfer Controller (DTC) and DMA Controller (DMAC) Activation

	TCI5V	TCNT5 overflow	Not possible	Not possible	-
	TCI5U	TCNT5 underflow	Not possible	Not possible	Low

Note: This table shows the initial state immediately after a reset. The relative channel priorities can be changed by the interrupt controller.

Operation

Each channel has a TCNT and TGR register. TCNT performs up-counting, and is also capable of free-running operation, synchronous counting, and external event counting. Each TGR can be used as an input capture register or output compare register.

- Buffer Operation
 - When TGR is an output compare register

When a compare-match occurs, the value in the buffer register for the relevant channel is transferred to TGR.

- When TGR is an input capture register

When input capture occurs, the value in TCNT is transfer to TGR and the value previously held in TGR is transferred to the buffer register.

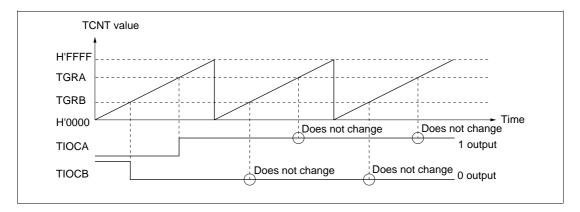

Waveform Output by Compare-Match

0, 1, or toggle output can be selected.

• Example of 0 Output/1 Output Operation

In this example, TCNT has been designated as a free-running counter, and settings have been made so that 0 is output by compare-match A, and 1 is output by compare-match B.

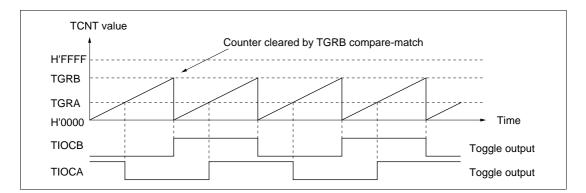

Example of 0 Output/1 Output Operation

• Example of Toggle Output

In this example, settings have been made so that TCNT counter clearing is performed by compare-match B, and output is toggled by both by compare-match A and compare-match B.

Example of Toggle Output Operation

PWM Modes

In PWM mode, PWM waveforms are output from the output pins. There are two PWM modes— PWM mode 1 with a maximum of 8-phase pulse output, and PWM mode 2 with a maximum of 15-phase pulse output.

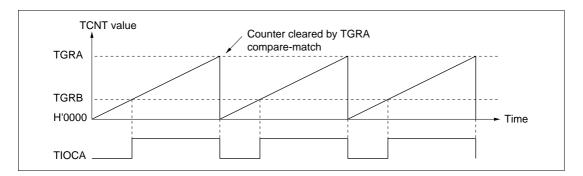

PWM Mode 1: PWM output is generated by pairing TGRA with TGRB and TGRC with TGRD.

In PWM mode 1, a maximum 8-phase PWM output is possible.

• Example of operation in PWM mode 1

In this example, TGRA compare-match is set as the TCNT clearing source, 0 is set for the TGRA initial output value and output value, and 1 is set as the TGRB output value. In this case, the value set in TGRA is the cycle, and the value set in TGRB is the duty.

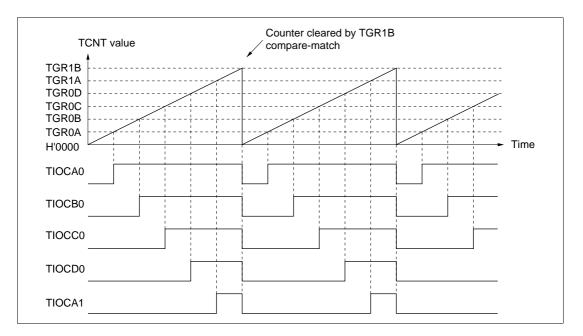

Operation in PWM Mode 1

PWM Mode 2: PWM output is generated using one TGR register as the cycle register and the others as duty registers. In PWM mode 2, a maximum 15-phase PWM output is possible by combined use with synchronous operation.

• Example of operation in PWM mode 2

In this example, synchronous operation is designated for channels 0 and 1, TGR1B comparematch is set as the TCNT clearing source, and 0 is set for the initial output value and 1 for the output value of the other TGR registers, to output a 5-phase PWM waveform. In this case, the value set in TGR1B is the cycle, and the value set in the other TGR registers is the duty.

Operation in PWM Mode 2

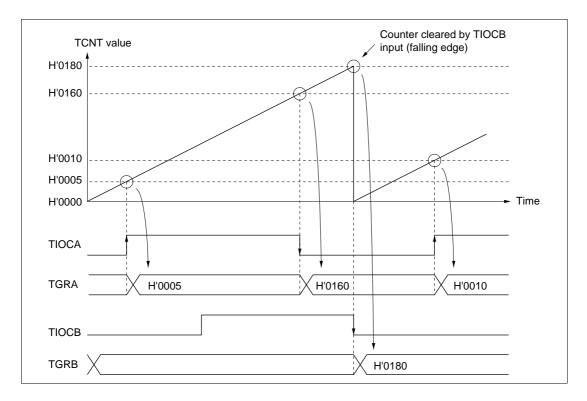

Input Capture Operation

The TCNT value can be transferred to TGR on detection of the TIOC pin input edge.

Rising edge, falling edge, or both edges can be selected as the input edge.

• Example of input capture operation

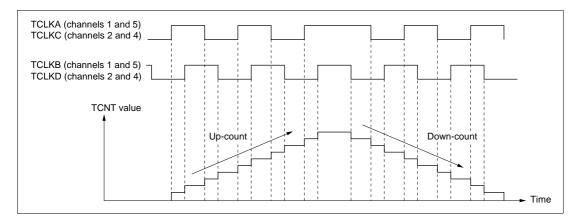

In this example, both rising and falling edges have been selected as the TIOCA pin input edge, falling edge has been selected as the TIOCB pin input edge, and counter clearing by TGRB input capture has been designated for TCNT.

Phase Counting Mode

In phase counting mode, the phase difference between two external clock inputs is detected and TCNT operates as an up/down-counter. There are four modes (phase counting modes 1 to 4) with different setting conditions. These modes can be set for channels 1, 2, 4, and 5.

• Example of Operation in Phase Counting Mode 1

• Up/Down-Count Conditions in Phase Counting Mode

TCLKA (Channels 1 and 5)	TCLKB (Channels 1 and 5)	Phase Counting Mode							
TCLKC (Channels 2 and 4)	TCLKD (Channels 2 and 4)	1	2	3	4				
High level	_ F	Up-count		_	Up-count				
Low level	P	_							
_ _	Low level	_			_				
T_	High level	_	Up-count	Up-count	_				
High level	T_	Down-count		Down-count	Down-count				
Low level		_		_	_				
	High level	_			_				
L	Low level	_	Down-count	_					
Legend									

F : Rising edge

Falling edge

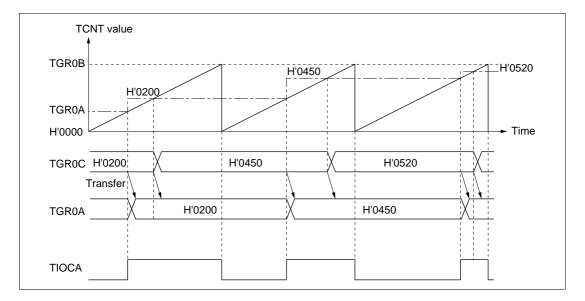

— : Don't care

Buffer Operation

Buffer operation, provided for channels 0 and 3, enables TGRC and TGRD to be used as buffer registers.

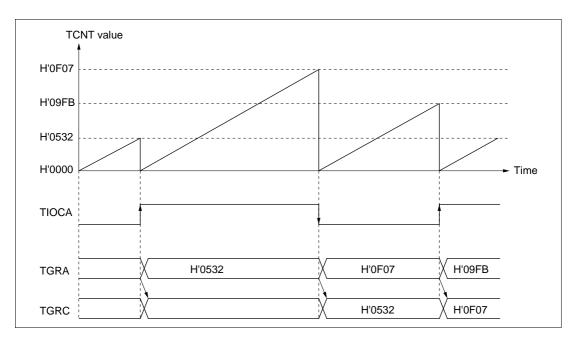

• Example of buffer operation (1) (When TGR is an output compare register) In this example, PWM mode 1 has been designated for channel 0, and buffer operation has been designated for TGRA and TGRC. The settings used are TCNT clearing by a comparematch B, 1 output at compare-match A, and 0 output at compare-match B. When a comparematch A occurs, the output is changed and the value in buffer register TGRC is simultaneously transferred to timer general register TGRA.

Example of Buffer Operation (1) (When TGR is an Output Compare Register)

• Example of buffer operation (2) (When TGR is an input capture register)

In this example, TGRA has been designated as an input capture register, and buffer operation has been designated for TGRA and TGRC. Counter clearing by TGRA input capture has been set for TCNT, and detection of both rising and falling edges has been selected for the TIOCA pin. When the TCNT value is stored in TGRA upon occurrence of input capture A, the value previously stored in TGRA is simultaneously transferred to TGRC.

Example of Buffer Operation (2) (When TGR is an Output Compare Register)

Cascading

In cascaded operation, two 16-bit counters for different channels are used together as a 32-bit counter. Channels 1 and 2, and channels 4 and 5, can be cascaded.

• Example of cascaded operation

In this example, counting upon TCNT2 overflow/underflow has been set for TCNT1, TGR1A and TGR2A have been designated as input capture registers, and TIOC pin rising edge detection has been selected. When a rising edge is input to the TIOCA1 and TIOCA2 pins simultaneously, the upper 16 bits of the 32-bit data are transferred to TGR1A, and the lower 16 bits to TGR2A.

Example of Cascaded Operation (32-bit Input Capture Operation)

TCNT1 clock —						
TCNT1	H'03A1	_χ		H'03A2		
TCNT2 clock —						
TCNT2	H'FFFF	χ	H'0000		_X	H'0001
TIOCA1, TIOCA2 —						
TGR1A			X	H'03A2		
TGR2A			χ	H'0000		

Synchronous Operation

When synchronous operation is designated for a channel, TCNT for that channel performs synchronous presetting and clearing. That is, when TCNT for a channel designated for synchronous operation is rewritten, the TCNT counters for the other channels are also rewritten at the same time. When any clearing condition occurs, the TCNT counters for the other channels are also cleared simultaneously.

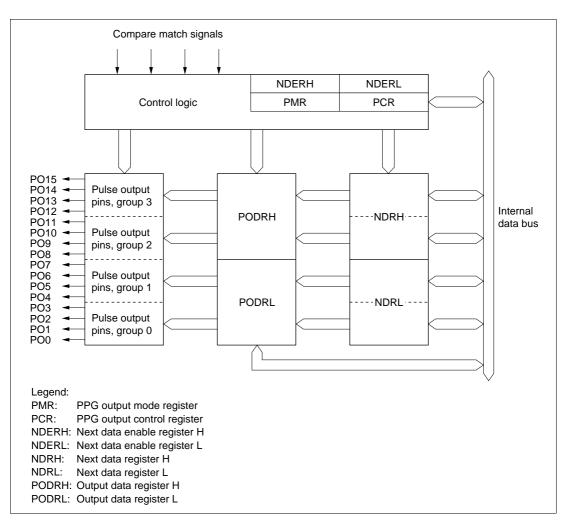

4.5 Programmable Pulse Generator (PPG)

The programmable pulse generator (PPG) can handle up to 16 outputs simultaneously, using a signal from the 16-bit timer-pulse unit (TPU) as its input.

Features

- 16-bit output data
 - Maximum 8-bit data can be output, and pulse output can be enabled on a bit-by-bit basis
- Four output groups
 - Output trigger signals can be selected in 4-bit groups to provide a maximum of two 4-bit outputs
- Selectable output trigger signals
 - Output trigger signals can be selected for each group from the compare match signals of four TPU channels
- Non-overlap operation
 - A non-overlap interval can be set between pulse outputs
- Can operate together with the data transfer controller (DTC) and DMA controller (DMAC)
 - The compare match signals selected as output trigger signals can activate the DTC or DMAC for sequential output of data without CPU intervention
- Settable inverted output
 - Inverted data can be output for each group
- Module stop mode can be set
 - As the initial setting, PPG operation is halted. Register access is enabled by exiting module stop mode

Block Diagram of PPG

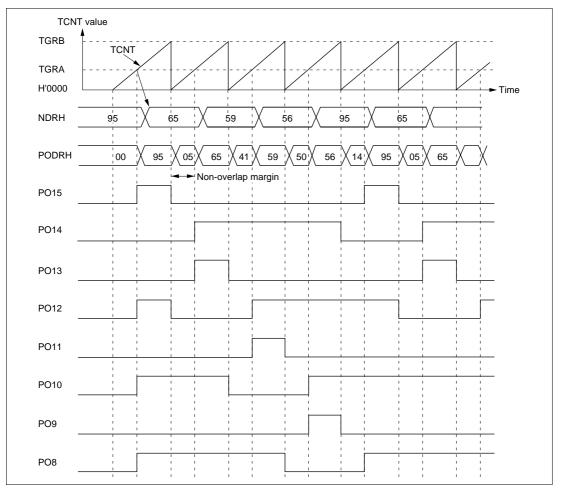

Example of Four-Phase Complementary Non-Overlapping Output

In this example, pulse output is used for four-phase complementary non-overlapping pulse output.

When a TGRB compare-match occurs, outputs change from 1 to 0. When a TGRA compare-match ocurs, outputs change from 0 to 1. Set the non-overlap margin in the TPU TGRA for which the output trigger is selected, and set the cycle in TGRB.

If the DTC or DMAC is set for activation by a TGIA interrupt, pulse output can be performed without imposing a load on the CPU.

Non-Overlapping Pulse Output Example (Four-Phase Complementary Non-Overlapping Output)

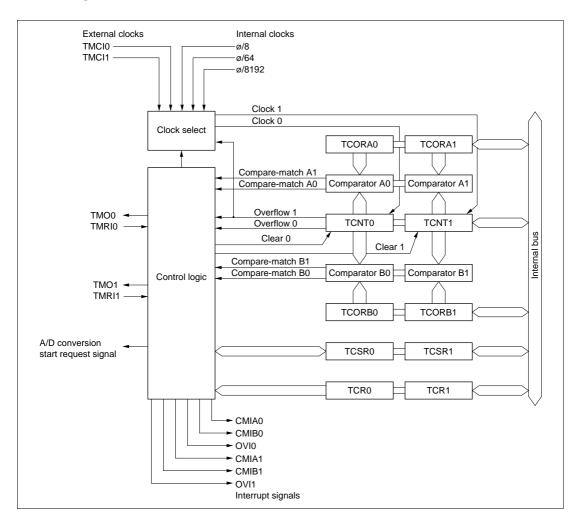

4.6 8-Bit Timer (TMR)

These series includes an 8-bit timer with two channels based on an 8-bit counter. The 8-bit timer can be used for a variety of applications as a multifunctional timer, including pulse output with an arbitrary duty cycle.

Features

- Selection of four input clock sources
 - The clock source can be selected from three internal clocks (ø/8, ø/64, or ø/8192) or an external clock (external event counting is possible).
- Counter clearing specification
 - The counters can be cleared on compare-match A or B, or by an external reset signal.
- Timer output controlled by combination of two compare-match signals
 - The combination of two independent compare-match signals provides for various applications, including pulse output or PWM output with any duty cycle.
- Provision for cascading of two channels
 - Operation as a 16-bit timer is possible, using channel 0 for the upper 8 bits and channel 1 for the lower 8 bits (16-bit count mode).
 - Channel 1 can be used to count channel 0 compare matches (compare match count mode).
- Three interrupt sources for each channel
 - There are two compare-match sources and one overflow source, capable of independent requests.
- A/D converter conversion start trigger can be generated
 - Channel 0 compare-match A signal can be used as an A/D converter conversion start trigger.
- Module stop mode can be set
 - As the initial setting, 8-bit timer operation is halted. Register access is enabled by exiting module stop mode.

Block Diagram

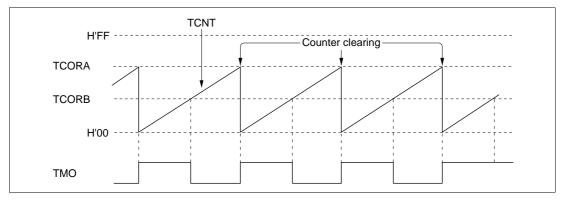

Channel	Interrupt Source	Description	DTC Activation	Priority *
0	CMIA0	Interrupt by CMFA	Possible	High
	CMIB0	Interrupt by CMFB	Possible	▲
	OVI0	Interrupt by OVF	Not possible	
1	CMIA1	Interrupt by CMFA	Possible	
	CMIB1	Interrupt by CMFB	Possible	
	OVI1	Interrupt by OVF	Not possible	Low

Interrupt Source and Data Transfer Controller (DTC) Activation

Note: * This table shows the initial state immediately after a reset. The relative channel priorities can be changed by the interrupt controller.

Example of Pulse Output

TCR is used to set counter clearing by a TCORA compare-match. The cycle is set in TCORA, and the duty in TCORB. The pulses shown below can be output continuously without software intervention.

Example of Pulse Output

4.7 Watchdog Timer (WDT)

These series have a single-channel on-chip watchdog timer (WDT) for monitoring system operation.

When this watchdog function is not needed, the WDT can be used as an interval timer.

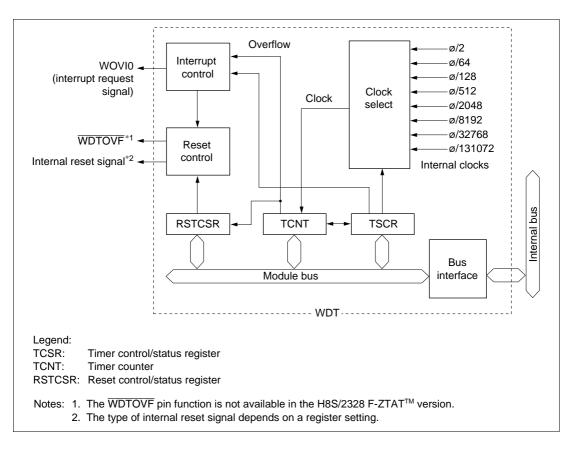

Features

- Switchable between watchdog timer mode and interval timer mode
- WDTOVF output when in watchdog timer mode*
 - If the counter overflows, the WDT outputs the $\overline{\text{WDTOVF}}$ signal externally. It is possible to select whether or not the entire series is reset at the same time.

Note: * The \overline{WDTOVF} pin function is not available in the H8S/2328 F-ZTATTM version.

- Interrupt generation when in interval timer mode
 - If the counter overflows, the WDT generates an interval timer interrupt.
- Choice of eight counter input clocks

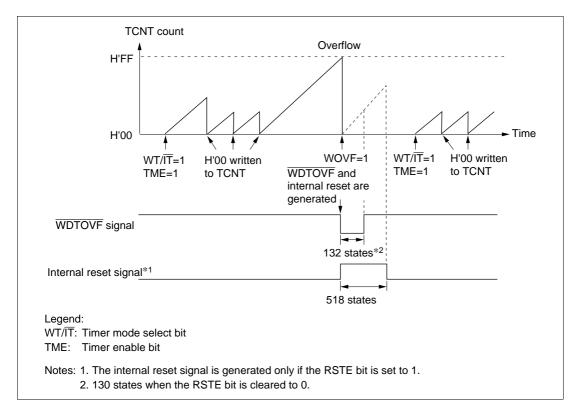

— ø/2, ø/64, ø/128, ø/512, ø/2048, ø/8192, ø/32768, ø/131072

Watchdog Timer Operation

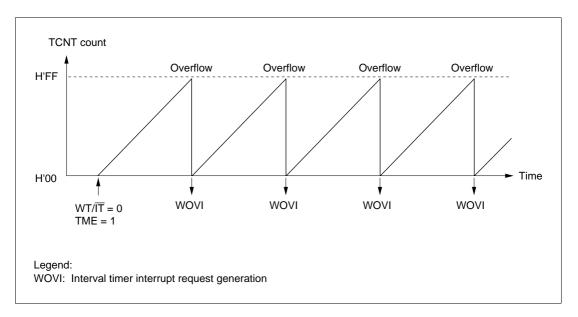

The example below shows this timer used as a watchdog timer. The timer counter (TCNT) starts counting up using the specified clock.

Watchdog Timer Operation

Interval Timer Operation

An example of the use of the WDT as an interval timer is shown here. The timer counter (TCNT) starts counting up on the specified clock, and an interval timer interrupt (WOVI) occurs each time TCNT overflows. This function can be used to generate interrupt requests at regular intervals.

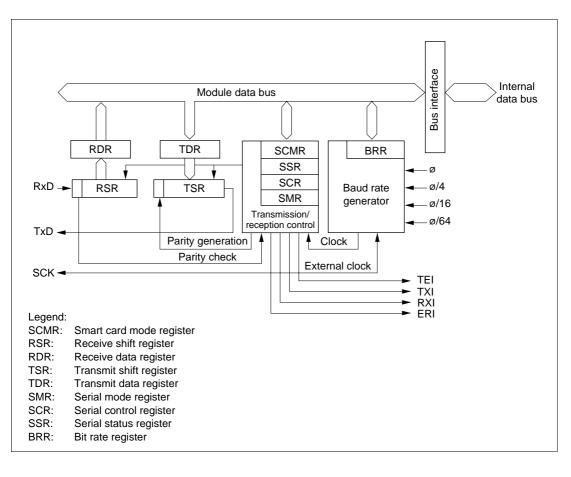

4.8 Serial Communication Interface (SCI)

These series have a serial communication interface (SCI) with three independent channels. All three channels have the same functions, and can handle both asynchronous and clocked synchronous serial communication. A function is also provided for serial communication between processors (multiprocessor communication function).

Features

- Choice of asynchronous or clocked synchronous serial communication mode
- Full-duplex communication capability
- Data register double-buffering enables continuous transmission/reception
- On-chip dedicated baud rate generator allows any bit rate to be selected
- Selection of on-chip baud rate generator or external clock input (SCK pin) as serial clock source
- Detection of three receive errors
 - Overrun errors, framing errors, and parity errors can be detected
- Break detection
- Four interrupt sources
 - Four interrupt sources—transmit data empty, transmission end, receive data full, and receive error—that can issue requests independently
 - The transmit data empty interrupt and receive data full interrupt can activate the DMA controller (DMAC) or data transfer controller (DTC) to execute data transfer
- Built-in multiprocessor communication function
- Selection of LSB-first or MSB-first transfer
 - This choice can be made regardless of the communication mode (with the exception of 7bit data transfer in asynchronous mode)
- Module stop mode can be set
 - As the initial setting, SCI operation is halted. Register access is enabled by exiting module stop mode.

SCI Interrupt Sources

Channel	Interrupt Source	Description	DTC Activation	DMAC Activation	Priority*
0	ERI	Interrupt due to receive error (ORER, FER, or PER)	Not possible	Not possible	High
	RXI	Interrupt due to receive data full (RDRF)	Possible	Possible	_
	TXI	Interrupt due to transmit data empty (TDRE)	Possible	Possible	_
	TEI	Interrupt due to transmission end (TEND)	Not possible	Not possible	_
1	ERI	Interrupt due to receive error (ORER, FER, or PER)	Not possible	Not possible	_
	RXI	Interrupt due to receive data full (RDRF)	Possible	Possible	_
	TXI	Interrupt due to transmit data empty (TDRE)	Possible	Possible	_
	TEI	Interrupt due to transmission end (TEND)	Not possible	Not possible	_
2	ERI	Interrupt due to receive error (ORER, FER, or PER)	Not possible	Not possible	_
	RXI	Interrupt due to receive data full (RDRF)	Possible	Not possible	_
	TXI	Interrupt due to transmit data empty (TDRE)	Possible	Not possible	_
	TEI	Interrupt due to transmission end (TEND)	Not possible	TBD	Low

Note: * This table shows the initial state immediately after a reset. Relative priorities among channels can be changed by means of the interrupt controller.

SCI Asynchronous Communication

Asynchronous mode is a serial communication mode in which synchronization is achieved on a character by character basis, using a start bit and one or two stop bits.

- Twelve serial data transfer formats
 - Data length: 7 or 8 bits
 - Stop bit length: 1 or 2 bits
 - Parity: Even/odd/none
 - Multiprocessor bit: 1 or 0
- Selection of on-chip baud rate generator or external clock from SCK pin as clock source
- Transmit/receive clock can be output from SCK pin
- Break detection
 - A break can be detected by reading the RxD pin level directly in case of a framing error
- Multiprocessor communication capability

Serial Transfer Formats and Frame Lengths in Asynchronous Mode

Legend:

S: Start bit

STOP: Stop bit

P: Parity bit

MPB: Multiprocessor bit

Multiprocessor Communication Function

A multiprocessor format, in which a multiprocessor bit is added to the transfer data, can be used for serial communication, enabling data transfer to be performed among a number of processors.

The transmitting station first sends the ID of the receiving station with which it wants to perform serial communication as data with a "1" MPB (multiprocessor bit) added. It then sends transmit data as data with a "0" MPB added.

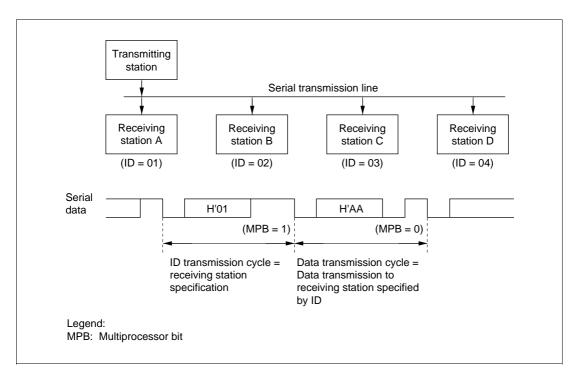

Receiving stations skip data until data with a "1" MPB is received. Each receiving station then compares that data with its own ID. The station whose ID matches then continues with reception, and accepts data. Stations whose ID does not match continue to skip the data until data with a "1" MPB is sent again.

SCI Synchronous Communication

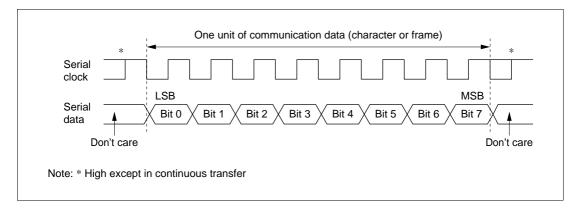

In synchronous mode, data is transmitted or received in synchronization with clock pulses, making it suitable for continuous, high-speed serial communication.

- Data length: 8 bits per character
- Overrun error detection
- Selection of on-chip baud rate generator or external clock from SCK pin as transmit/receive clock source
- Selection of LSB-first or MSB-first transfer
- Communication is possible with chips provided with a synchronous mode, such as the H8 Series, HD64180, and HD6301

Example of Inter-Processor Communication Using Multiprocessor Format (Transmission of Data H'AA to Receiving Station A)

Data Format in Synchronous Communication

	Operating Frequency Ø (MHz)													
Bit Rate	ø = 2		ø = 4		ø = 8		ø = 10		ø = 16		ø = 20		ø = 25

BRR Settings for Various Bit Rates (Clocked Synchronous Mode)

Operating Frequency ø (MHz)

Note: As far as possible, the setting should be made so that the error is no more than 1%.

Legend:

Blank: Cannot be set.

- -: Can be set, but there will be a degree of error.
 - *: Continuous transfer is not possible.

The BRR setting is found from the following formulas.

Asynchronous mode:

$$\mathsf{N} = \frac{\phi}{64 \times 2^{2\mathsf{n}-1} \times \mathsf{B}} \times 10^6 - 1$$

Clocked synchronous mode:

$$\mathsf{N} = \frac{\phi}{8 \times 2^{2\mathsf{n}-1} \times \mathsf{B}} \times 10^6 - 1$$

Where B: Bit rate (bit/s)

- N: BRR setting for baud rate generator ($0 \le N \le 255$)
- ø: Operating frequency (MHz)
- n: Baud rate generator input clock (n = 0 to 3)(See the table below for the relation between n and the clock.)

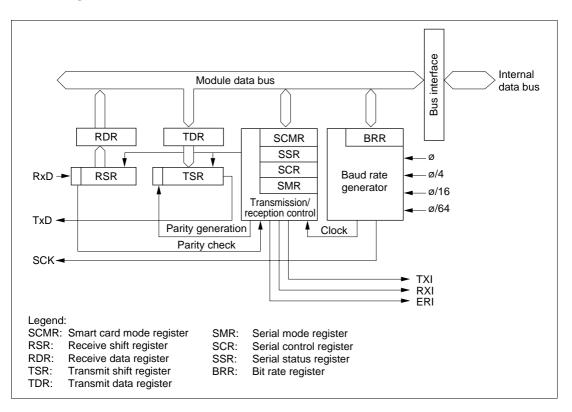

n	Clock
0	ø
1	ø/4
2	ø/16
3	ø/64

4.9 Smart Card Interface

The SCI supports a smart card interface as an IC card interface serial communication function conforming to ISO/IEC7816-3 (Identification Card).

Features

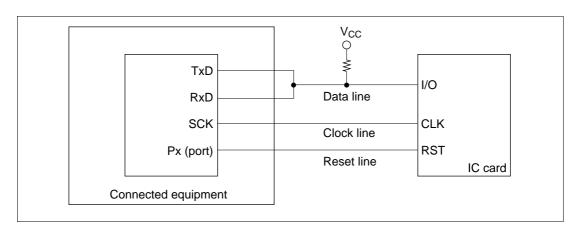

- Asynchronous mode
 - Data length: 8 bits
 - Parity bit generation and checking
 - Transmission of error signal (parity error) in receive mode
 - Error signal detection and automatic data retransmission in transmit mode
 - Direct convention and inverse convention both supported
- Internal baud rate generator allows any bit rate to be selected
- Three interrupt sources
 - Three interrupt sources—transmit data empty, receive data full, and transmit/receive error—that can issue requests independently
 - The transmit data empty interrupt and receive data full interrupt can activate the DMA controller (DMAC) or data transfer controller (DTC) to execute data transfer

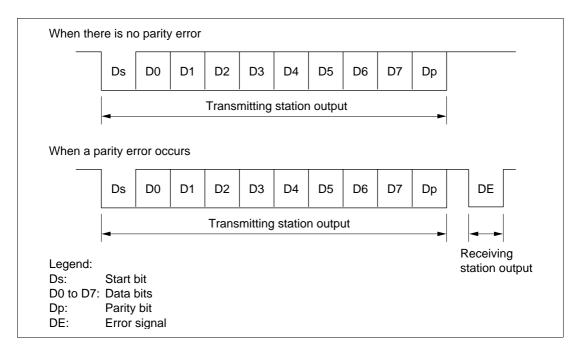

Operation

- Overview
 - Only asynchronous communication is supported, with one frame consisting of 8-bit data plus and a parity bit.
 - In transmission, a guard time of at least 2 etu (Elementary Time Unit: the time for transfer of one bit) is left between the end of the parity bit and the start of the next frame.
 - If a parity error is detected during reception, a low error signal level is output for a 1 etu period 10.5 etu after the start bit (except in block transfer mode).
 - If the error signal is sampled during transmission, the same data is transmitted automatically after the elapse of 2 etu or longer (except in block transfer mode).

Schematic Diagram of Smart Card Interface Pin Connections

Smart Card Interface Data Format

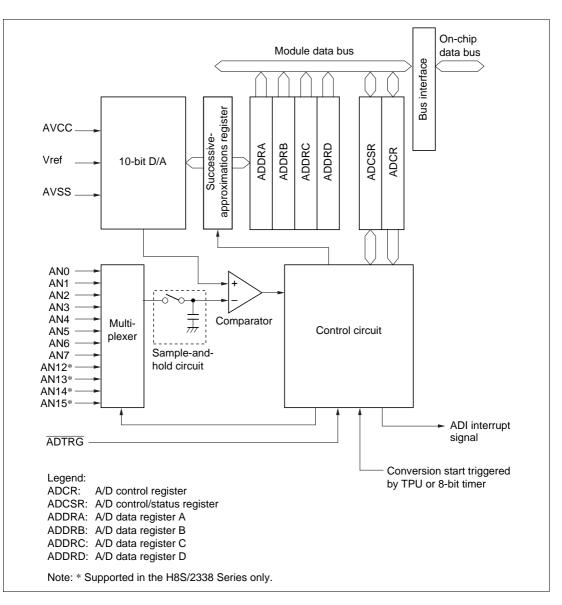

4.10 A/D Converter

These series incorporate an on-chip A/D converter with 10-bit precision. Analog signals can be input on up to 12 channels in the H8S/2338 Series and up to eight channels in the H8S/2328 Series.

Features

- 10-bit resolution
- Input channels
 - 12 in the H8S/2338 Series
 - Eight in the H8S/2328 Series
- Settable analog conversion voltage range
 - Conversion of analog input from 0 V to V_{ref} , with the reference voltage pin (Vref) as the analog reference voltage
- High-speed conversion
 - Minimum conversion time: 6.7 µs per channel (at 20 MHz operation)
- Selection of single mode or scan mode
 - Single mode: A/D conversion of one channel
 - Scan mode: continuous A/D conversion on one to four channels
- Three kinds of conversion start
 - Selection of software or timer conversion start trigger (TPU or 8-bit timer), or ADTRG pin
- Four data registers
 - Conversion results held in a data register for each channel
- Sample and hold function
- A/D conversion end interrupt generation
 - A/D conversion end interrupt (ADI) request can be generated at the end of A/D conversion
- Module stop mode can be set
 - As the initial setting, A/D converter operation is halted. Register access is enabled by exiting module stop mode.

Input Channel Setting

The analog input is performed by means of the scan mode bit (SCAN) and channel select bits (CH3 to CH0) in ADCSR.

				Description					
CH3*	CH2	CH1	CH0	Single Mode (SCAN = 0)	Scan Mode (SCAN = 1)				
0	0	0	0	Illegal setting	Illegal setting				
			1	Illegal setting	Illegal setting				
		1	0	Illegal setting	Illegal setting				
			1	Illegal setting	Illegal setting				
	1	0	0	AN12	AN12				
			1	AN13	AN12, AN13				
		1	0	AN14	AN12 to AN14				
			1	AN15	AN12 to AN15				
1	0	0	0	AN0 (initial value)	AN0				
			1	AN1	ANO, AN1				
		1	0	AN2	AN0 to AN2				
			1	AN3	AN0 to AN3				
	1	0	0	AN4	AN4				
			1	AN5	AN4, AN5				
		1	0	AN6	AN4 to AN6				
			1	AN7	AN4 to AN7				

Note: * For the H8S/2328 Series, 1 should be written to CH3 as there are only eight analog input channels.

Operation

The successive comparison method is used for A/D conversion, with a 10-bit resolution. There are two operating modes—single or scan.

• Single Mode

Single mode is selected when A/D conversion is to be performed on a single channel only. A/D conversion is started when the ADST bit is set to 1, according to the specified A/D conversion start condition.

On completion of conversion, the ADF flag is set to 1. If the ADIE bit is set to 1 at this time, an ADI interrupt request is generated.

• Scan Mode

Scan mode is selected when A/D conversion is to be performed repeatedly on a number of channels.

Once the ADST bit is set to 1 according to the specified A/D conversion start condition, A/D conversion is performed repeatedly on the selected channel until the ADST bit is cleared to 0 by software.

An ADI interrupt request can be generated on completion of the first conversion operation for all the selected input channels.

4.11 D/A Converter

These series have an on-chip D/A converter with 8-bit-precision. Analog signals can be output on up to four channels in the H8S/2338 Series and up to two channels in the H8S/2328 Series.

Features

- Eight-bit resolution
- Output channels
 - Four in the H8S/2338 Series
 - Two in the H8S/2328 Series
- Maximum conversion time of 10 µs (with 20 pF load capacitance)
- Output voltage of 0 V to V_{ref}
- D/A output hold function in software standby mode
- Module stop mode can be set
 - As the initial setting, D/A converter operation is halted. Register access is enabled by exiting module stop mode.

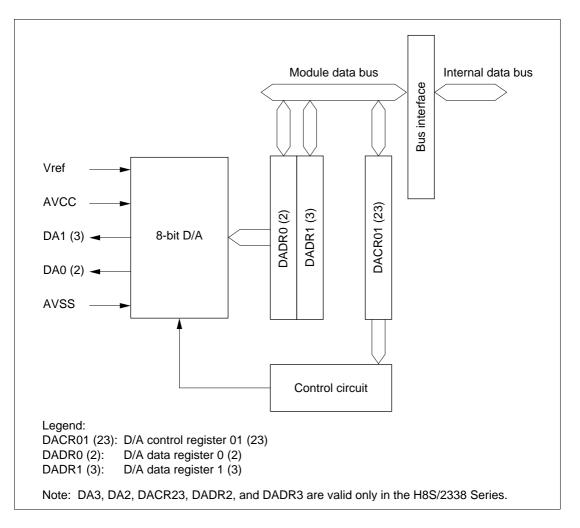

Operation

D/A converter operation is enabled by setting the D/A output enable bit to 1. While this bit is set to 1, DADR contents are constantly converted and output to the corresponding pin.

The output value is:

 $\frac{\text{DADR contents}}{256} \times V_{\text{ref}}$

Block Diagram

4.12 I/O Ports

The H8S/2338 Series has 15 input/output ports (ports 1, 2, 3, 5, (P50–P53), 6, 7, 8, 9, A, B, C, D, E, F, and G) and two input ports (ports 4 and 5 (P54–P57).

The H8S/2328 Series has 12 input/output ports (ports 1, 2, 3, 5, 6, A, B, C, D, E, F, and G) and one input port (port 4).

Each port includes a data direction register (DDR) that controls input/output, a data register (DR) that stores output, and a port register (PORT) used to read the pin states.

Ports A to E incorporate a MOS input pull-up, and in addition to DDR and DR, have a MOS input pull-up control register (PCR) that turns the MOS input pull-up on or off.

		PF0/BREQ	When BRLE =	1: BREQ input	, BACK output	

Port	Description	Pins	Mode 4	Mode 5	Mode 6	Mode 7
Port G	• 5-bit I/O	PG4/CS0	When DDR = 0)*1: input port		I/O port
	port		When DDR = 1	I*2: CS0 output		
		PG3/CS1	When DDR = 0) (after reset): ii	nput port	
		PG2/CS2	When CS167E	= 0: PG3 is I/C) port	
	PG1/ $\overline{CS3}$ When CS167E = 1 and DDR = 1: $\overline{CS1}$ output				= 1: CS1	
			When CS167E port			
			When CS25E = ports			
			When CS25E = $\overline{CS3}$ outputs	= 1 and DDR =	1: $\overline{\text{CS2}}$ and	
			When CS25E = PG1 input port	= 1 and DDR = s	0: PG2 and	
		PG0/CAS		set: CAS output		
			Otherwise (afte	er reset): I/O po	ort	

Notes: 1. After a reset in mode 6

2. After a reset in mode 4 or 5

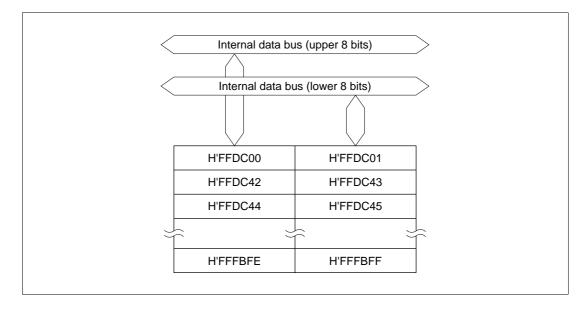

4.13 RAM

The H8S/2338, H8S/2337, H8S/2332, H8S/2328, H8S/2327, H8S/2323, and H8S/2322 have 8 kbytes of on-chip high-speed static RAM.

The on-chip RAM is connected to the bus master by a 16-bit data bus, enabling both byte data and word data to be accessed in one state. This makes it possible to perform fast word data transfer.

The on-chip RAM can be enabled or disabled by means of the RAM enable bit (RAME) in the system control register (SYSCR).

Block Diagram of RAM (8-Kbyte Case)

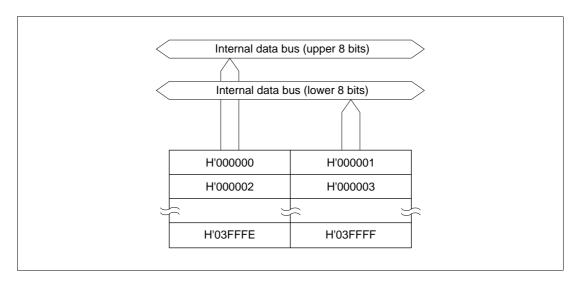

4.14 ROM

The H8S/2338 and H8S/2328 have 256 kbytes of on-chip flash memory or mask ROM, and the H8S/2337 and H8S/2327 have 128 kbytes of on-chip mask ROM, and H8S/2323 have 32 kbytes of on-chip mask ROM.

The ROM is connected to the bus master by a 16-bit data bus, enabling both byte data and word data to be accessed in one state. This allows rapid instruction fetches and improves processing speed.

In addition to erasing and programming with a dedicated PROM programmer, the flash memory version can also be erased and programmed on-board.

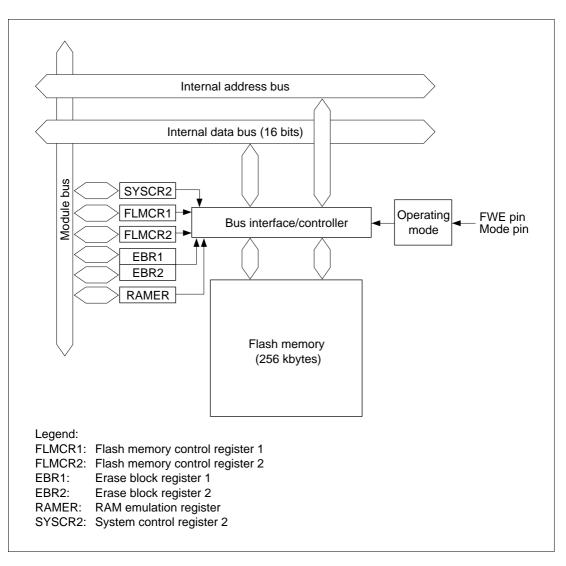

ROM Block Diagram (H8S/2338, H8S/2328)

On-chip ROM is enabled or disabled by means of the mode pins (MD2 to MD0) and the EAE bit in BCRL.

Features of Flash Memory

- Four operating modes
 - Program mode
 - Erase mode
 - Program-verify mode
 - Erase-verify mode
- Programming/erase methods
 - 128 bytes programmed simultaneously
 - 4-kbyte, 32-kbyte, or 64-kbyte units can be set for block erasing
- Programming/erase times
 - Programming time: TBD per 128-byte programming operation TBD per byte
 - Erase time: TBD per block
- Reprogramming up to 100 times
- On-board programming modes
 - Boot mode
 - User program mode
- Automatic bit rate adjustment
 - With data transfer in boot mode, the bit rate of the chip can be automatically adjusted to match the transfer bit rate of the host
- Flash memory emulation by RAM
 - Real-time programming of flash memory can be emulated by overlapping part of RAM onto flash memory
- Protect modes
 - There are three protect modes, hardware, software, and error protect, which allow protected status to be designated for flash memory program/erase/verify operations
- Writer mode
 - On-board programming mode and writer mode, using a PROM programmer, are available as flash memory program/erase modes

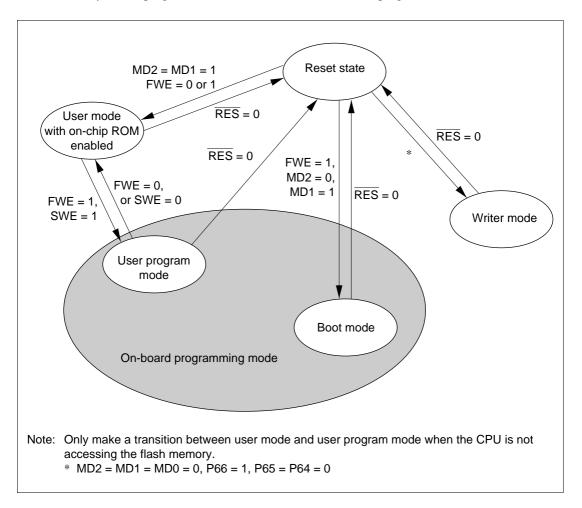

Block Diagram of Flash Memory (H8S/2338 and H8S/2328)

Mode Transitions

When the mode pins and FWE pins are set in the reset state and a reset-start is executed, the MCU enters one of the operating modes as shown in the figure below. In user mode, flash memory can be read but not programmed or erased.

Flash memory can be programmed and erased in boot mode, user program mode, and writer mode.

Section 5 Power-Down Modes

In addition to the normal program execution state, the these series have power-down modes in which operation of the CPU and oscillator is halted and power dissipation is reduced. Low-power operation can be achieved by individually controlling the CPU, on-chip supporting modules, and so on.

These series operating modes are as follows:

- 1. High-speed mode
- 2. Medium-speed mode
- 3. Sleep mode
- 4. Module stop mode
- 5. Software standby mode
- 6. Hardware standby mode

Of these, 2 to 6 are power-down modes. Sleep mode is a CPU mode, medium-speed mode is a CPU and bus master mode, and module stop mode is an on-chip supporting module mode (including bus masters other than the CPU). A combination of certain of these modes can be set.

Medium-Speed Mode: When bits SCK2, SCK1, and SCK0 in the system clock control register (SCKCR) are set to 1, medium-speed mode is entered as soon as the current bus cycle ends. In medium-speed mode, the bus masters—the CPU, DMAC, and DTC—operate on the operating clock ($\phi/2$, $\phi/4$, $\phi/8$, $\phi/16$, or $\phi/32$) specified by bits SCK2 to SCK0. However, on-chip peripheral functions other than the bus masters operate on the high-speed clock (ϕ).

In medium-speed mode, a bus access is executed in the specified number of states with respect to the bus master operating clock. (For example, if $\emptyset/4$ is selected as the operating clock, on-chip memory is accessed in four states, and internal I/O registers in eight states.)

Medium-speed mode is cleared by clearing bits SCK2 to SCK0 to 0. High-speed mode is restored at the end of the current bus cycle.

Sleep Mode: If a SLEEP instruction is executed when the SSBY bit in the system standby register (SBYCR) is cleared to 0, the CPU enters sleep mode. In sleep mode, CPU operation stops but the contents of the CPU's internal registers are retained. Other peripheral functions do not stop.

Sleep mode is cleared by a reset or any interrupt, and the CPU returns to the normal program execution state via the exception handling state.

Module Stop Mode: Module stop mode can be used to start and stop individual on-chip peripheral modules.

When the MSTP bit corresponding to a particular peripheral function in the module stop control register (MSTPCR) is set to 1, operation of the specified module stops at the end of the bus cycle and a transition is made to module stop mode. The CPU continues operating independently.

When the corresponding MSTP bit is cleared to 0, module stop mode is cleared and the module starts operating at the end of the bus cycle.

In module stop mode, the internal states of modules other than the SCI and A/D are retained.

After a reset, all modules except the DMAC and DTC are in module stop mode.

Software Standby Mode: If a SLEEP instruction is executed when the SSBY bit in SBYCR is set to 1, software standby mode is entered. In this mode, the CPU, on-chip peripheral functions, and oscillator all stop. However, the contents of the CPU's internal registers, RAM data, and the states of on-chip peripheral functions other than the SCI, A/D and I/O ports are retained.

Software standby mode is cleared by a reset or an external interrupt. After the elapse of the oscillation stabilization time, the program execution mode is restored via the exception handling state.

As the oscillator is stopped in this mode, power consumption is extremely low.

Hardware Standby Mode: When the STBY pin is driven low, a transition is made to hardware standby mode from any state.

In hardware standby mode, all functions enter the reset state and stop operation, resulting in extremely low power consumption. As long as the prescribed voltage is supplied, on-chip RAM data is retained. I/O ports are set to the high-impedance state.

Hardware standby mode is cleared by means of the $\overline{\text{STBY}}$ pin and the $\overline{\text{RES}}$ pin. When the $\overline{\text{STBY}}$ pin is driven high while the $\overline{\text{RES}}$ pin is low, the reset state is entered and clock oscillation is started. When the $\overline{\text{RES}}$ pin is subsequently driven high, the program execution state is restored via reset exception handling.

In this mode, as in software standby mode, power consumption is extremely low since the oscillator is stopped.

Chip Internal States in Each Mode

Operating	Transition	Clearing			CPU	M	odules	
Mode	Condition	Condition	Oscillator		Registers		Registers	I/O Ports
High speed mode	Control register	Control register	Functions	High speed	Functions	High speed	Functions	High speed
Medium- speed mode	Control register	Control register	Functions	Medium speed	Functions	High/ medium speed *		High speed
Sleep mode	Instruction	Interrupt	Functions	Halted	Retained	High speed	Functions	High speed
Module stop mode	Control register	Control register	Functions	High/ medium speed	Functions	Halted	Retained/ reset *2	Retained
Software standby mode	Instruction	External interrupt	Halted	Halted	Retained	Halted	Retained/ reset * ²	Retained
Hardware standby mode	Pin	Pin	Halted	Halted	Undefined	Halted	Reset	High impedance

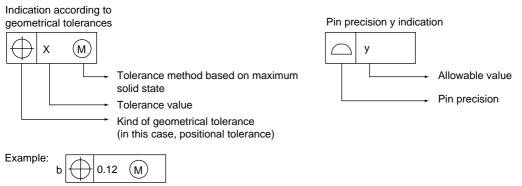

Notes: 1. The bus master operates on the medium-speed clock, and other on-chip supporting modules on the high-speed clock.

2. The SCI and A/D converter are reset, and other on-chip supporting modules retain their state.

Appendix

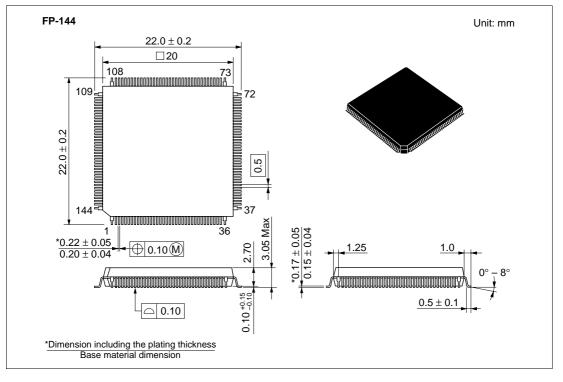

Packages

Package Dimension Diagrams (Unit: mm)

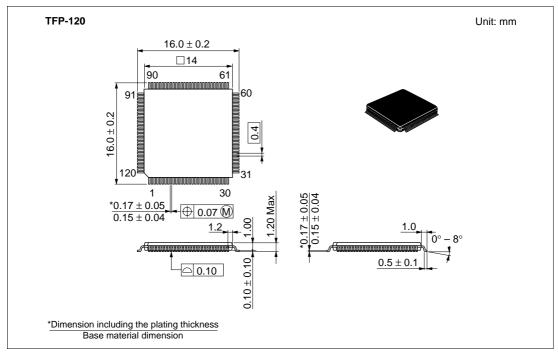

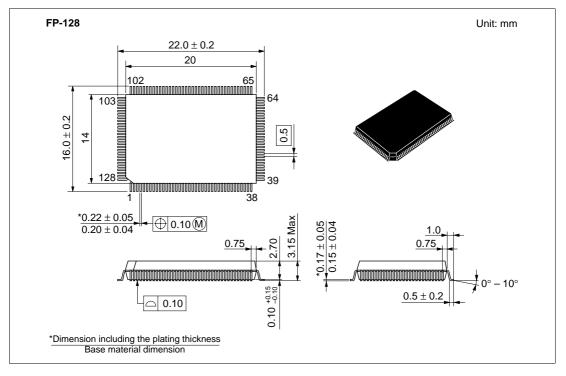

This indicates that the allowable pin displacement from the true central position is 0.12 mm when pin width b is the maximum dimension. If b is smaller than the maximum dimension, the tolerance can be extended accordingly.
