

5-V Low-Drop Fixed Voltage Regulator

TLE 4271

Features

- Output voltage tolerance $\leq \pm 2\%$
- Low-drop voltage
- Integrated overtemperature protection
- Reverse polarity protection
- Input voltage up to 42 V
- Overvoltage protection up to 65 V (\leq 400 ms)
- Short-circuit proof
- · Suitable for use in automotive electronics
- Wide temperature range
- Adjustable reset and watchdog time

Functional Description

It is a 5-V low-drop fixed-voltage regulator. The maximum input voltage is 42 V (65 V, \leq 400 ms). Up to an input voltage of 26 V and for an output current up to 550 mA it regulates the output voltage within a 2 % accuracy. The short circuit protection limits the output

current of more than 650 mA. The IC can be switched off via the inhibit input. An integrated watchdog monitors the connected controller. The device incorporates overvoltage protection and temperature protection that disables the circuit at unpermissibly high temperatures.

Pin Configuration

(top view)

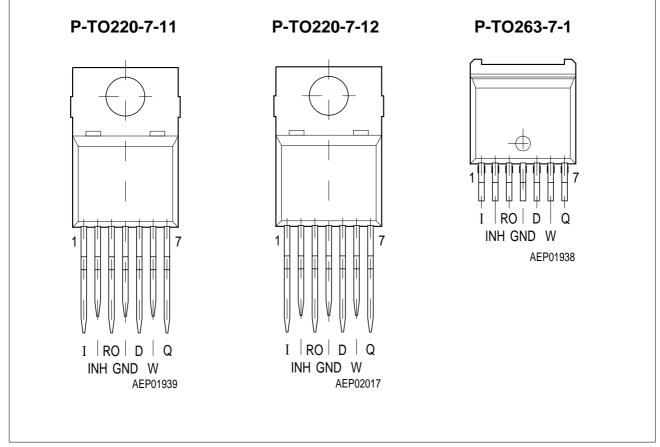

Figure 1

Pin Definitions and Functions

Pin	Symbol	Function
1	Ι	Input; block to ground directly on the IC with ceramic capacitor.
2	INH	Inhibit
3	RO	Reset Output ; the open collector output is connected to the 5 V output via an integrated resistor of 30 k Ω .
4	GND	Ground
5	D	Reset Delay ; connect a capacitor to ground for delay time adjustment.
6	W	Watchdog Input
7	Q	5-V Output ; block to ground with 22 μ F capacitor, ESR < 3 Ω .

Application Description

The IC regulates an input voltage in the range of 5.5 V < $V_{\rm I}$ < 36 V to $V_{\rm Qnom}$ = 5.0 V. Up to 26 V it produces a regulated output current of more than 550 mA. Above 26 V the save-operating-area protection allows operation up to 36 V with a regulated output current of more than 300 mA. Overvoltage protection limits operation at 42 V. The overvoltage protection hysteresis restores operation if the input voltage has dropped below 36 V. The IC can be switched off via the inhibit input, which causes the quiescent current to drop below 50 μ A. A reset signal is generated for an output voltage of $V_{\rm Q}$ < 4.5 V. The watchdog circuit monitors a connected controller. If there is no positive-going edge at the watchdog input within a fixed time, the reset output is set to low. The delay for power-on reset and the maximum permitted watchdog-pulse period can be set externally with a capacitor.

Design Notes for External Components

An input capacitor $C_{\rm I}$ is necessary for compensation of line influences. The resonant circuit consisting of lead inductance and input capacitance can be damped by a resistor of approx. 1 Ω in series with $C_{\rm I}$. An output capacitor $C_{\rm Q}$ is necessary for the stability of the regulating circuit. Stability is guaranteed at values of $C_{\rm Q} \ge 22 \,\mu\text{F}$ and an ESR of < 3 Ω .

Circuit Description

The control amplifier compares a reference voltage, which is kept highly accurate by resistance adjustment, to a voltage that is proportional to the output voltage and drives the base of a series transistor via a buffer. Saturation control as a function of the load current prevents any over-saturation of the power element.

If the output voltage decreases below 4.5 V, an external capacitor $C_{\rm D}$ on pin 4 (D) will be discharged by the reset generator. If the voltage on this capacitor $V_{\rm D}$ drops below $V_{\rm DRL}$, a reset signal is generated on pin 2 (RO), i.e. reset output is set low. If the output voltage rises above 4.5 V, $C_{\rm D}$ will be charged with constant current. After the power-on-reset time $V_{\rm D}$ reaches $V_{\rm DU}$ and the reset output will be set high again. The value of the power-on-reset time can be set within a wide range depending on the capacity of $C_{\rm D}$. The value of the pull-up resistor at reset output is typically 30 k Ω .

After $V_{\rm D}$ has reached the voltage $V_{\rm DU}$ and reset was set to high, the watchdog circuit is enabled and discharges $C_{\rm D}$ with a constant current. If there is no positive-going edge observed at watchdog input, $C_{\rm D}$ will be discharged down to $V_{\rm DWL}$. Then reset will be set low and the watchdog circuit will be disabled. $C_{\rm D}$ will be charged with the current as at power-on reset until $V_{\rm D}$ reaches $V_{\rm DU}$ and reset will be set high again.

If a watchdog pulse will be observed before $C_{\rm D}$ is discharged down to $V_{\rm DWL}$, the watchdog circuit will be enabled and $C_{\rm D}$ will be charged too, but reset will not be set low. After $V_{\rm D}$ has reached $V_{\rm DU}$, the periodical behavior starts again.

The IC also incorporates a number of internal circuits for protection against:

- Overload
- Overvoltage
- Overtemperature
- Reverse polarity

Temperatures					
Junction temperature	T _j	_	150	°C	_
Storage temperature	T_{stg}	- 50	150	°C	

Optimum reliability and life time are guaranteed if the junction temperature does not exceed 125 °C in operating mode. Operation at up to the maximum junction temperature of 150 °C is possible in principle. Note, however, that operation at the maximum permitted ratings could affect the reliability of the device.
