# TEA3718
TEA3718S

STEPPER MOTOR DRIVER

- HALF-STEP AND FULL-STEP MODE
- BIPOLAR DRIVE OF STEPPER MOTOR FOR MAXIMUM MOTOR PERFORMANCE
- BUILT-IN PROTECTION DIODES
- WIDE RANGE OF CURRENT CONTROL 5 TO 1500 mA
- WIDE VOLTAGE RANGE 10 TO 50 V
- DESIGNED FOR UNSTABILIZED MOTOR SUPPLY VOLTAGE
- CURRENT LEVELS CAN BE SELECTED IN STEPS OR VARIED CONTINUOUSLY
- THERMAL OVERLOAD PROTECTION
- ALARM OUTPUT OR PRE-ALARM OUTPUT (see internal table)

DESCRIPTION

The TEA3718 and TEA3718S are bipolar monolithic integrated circuits intended to control and drive the current in one winding of a bipolar stepper motor. The circuits consist of an LS-TTL compatible logic input, a current sensor, a monostable and an output stage with built-in protection diodes. Two TEA3718 or TEA3718S and a few external components form a complete control and drive unit for LS-TTL or microprocessor-controlled stepper motor systems.

PIN FUNCTIONS

Name	Function
OUT B	Output Connection (with pin OUTA). The output stage is a "H" bridge formed by four transistors and four diodes suitable for switching applications.
PULSE TIME	A parallel RC network connected to this pin sets the OFF time of the lower power transistors. The pulse generator is a monostable triggered by the rising edge of the output of the comparators ($t_{off} = 0.69\ R_T C_T$).
$V_S(B)$	Supply Voltage Input for Half Output Stage
GND	Ground Connection. In SO-20L and Powerdip these pins also conduct heat from die to printed circuit copper.
V_{SS}	Supply Voltage Input for Logic Circuitry
IN1	This pin and pin IN0 are logic inputs which select the outputs of three comparators to set the current level. Current also depends on the sensing resistor and reference voltage. See truth table.
PHASE	This TTL-compatible logic input sets the direction of current flow through the load. A high level causes current to flow from OUT A (source) to OUT B (sink). A Schmitt trigger on this input provides good noise immunity and a delay circuit prevents output stage short circuits during switching.
IN0	See INPUT 1
COMPARATOR INPUT	Input connected to the three comparators. The voltage across the sense resistor is feedback to this input through the low pass filter $R_C C_C$. The lower power transistor are disabled when the sense voltage exceeds the reference voltage of the selected comparator. When this occurs the current decays for a time set by $R_T C_T$, $T_{off} = 0.69\ R_T C_T$.
REFERENCE	A voltage applied to this pin sets the reference voltage of the three comparators. Reference voltage with the value of R_S and the two inputs IN0 and IN1 determines the output current.
$V_S(A)$	Supply voltage input for half output stage
OUT A	See pin OUT B
SENSE RESISTOR	Connection to lower emitters of output stage for insertion of current sense resistor
ALARM	When T_j reaches T1°C the alarm output becomes low (TEA3718SP)
PRE-ALARM	When T_j reaches T2°C the prealarm output becomes low (T2<T1) (TEA3718SFP)

FUNCTIONAL BLOCKS
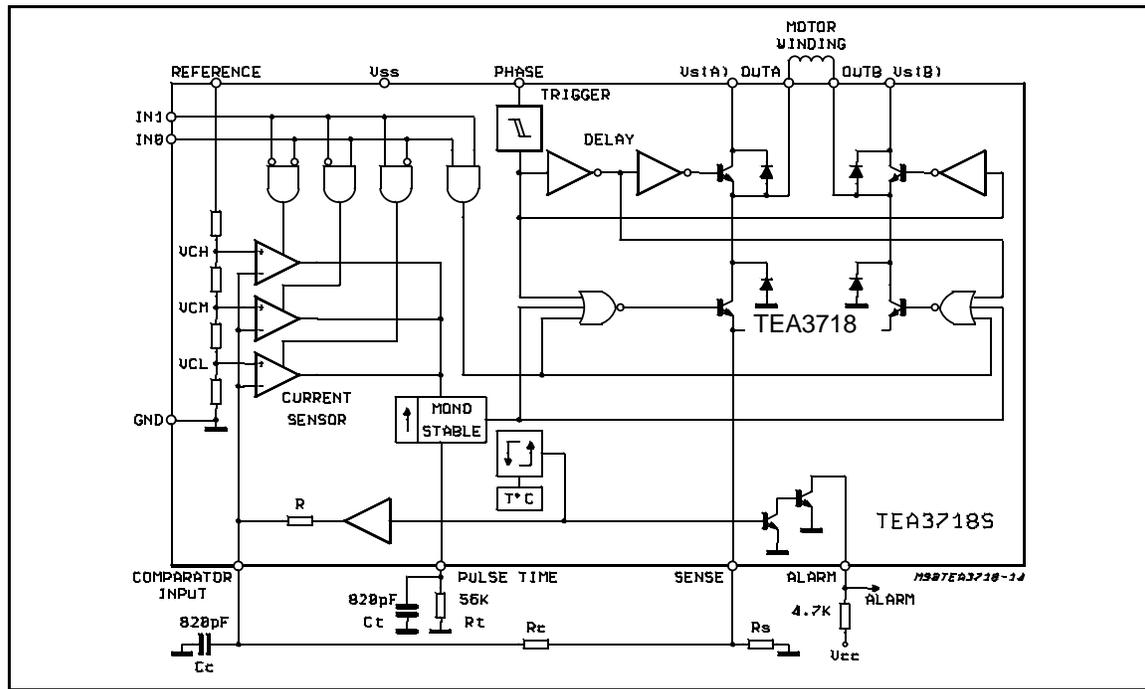

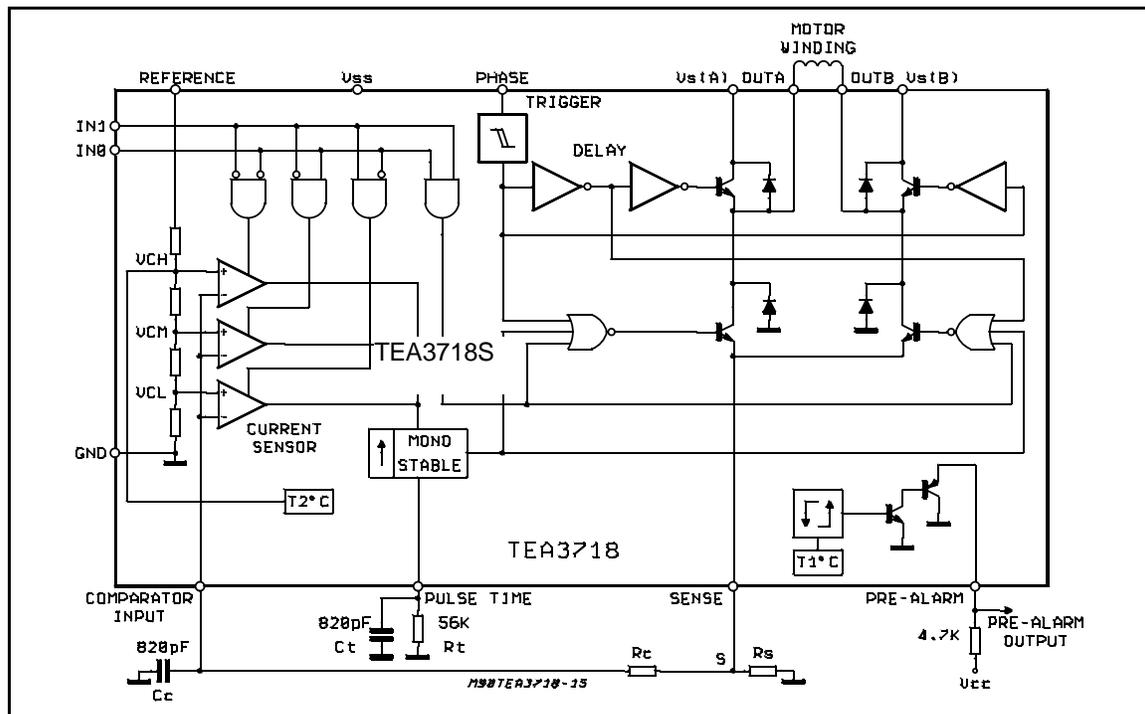

Figure A: ALARM OUTPUT (TEA3718SP - TEA3718DP)

Figure B: PRE-ALARM OUTPUT (TEA3718SDP - TEA3718SFP)

ALARM OUTPUTS (TEA3718SP - TEA3718DP)
The alarm output becomes low when the junction temperature reaches T°C.
When an alarm condition occours, parts of the supply voltage (dividing bridge R - R_C) is fed to the comparator input pin (Fig. A)
Depending of the R_CC value the behaviour of the circuit is different on alarm condition:

1) $R_C > 80\Omega \Rightarrow$ the output stage is switched off

2) $R_C > 60\Omega \Rightarrow$ the current in the motor windings is reduced according to the approximate formula: (see also fig. E and F)

$$I_m = \frac{V_{TH}}{R_S} - \frac{V_{CC}}{R + R_C} \bullet \frac{R_C}{R_S}$$

with V_{TH} = Threshold of the comparator (V_{CH}, V_{CM}, V_{CL}) R = 700Ω (typical)

For several Multiwatt packages a common detection can be obtained as in Fig. D
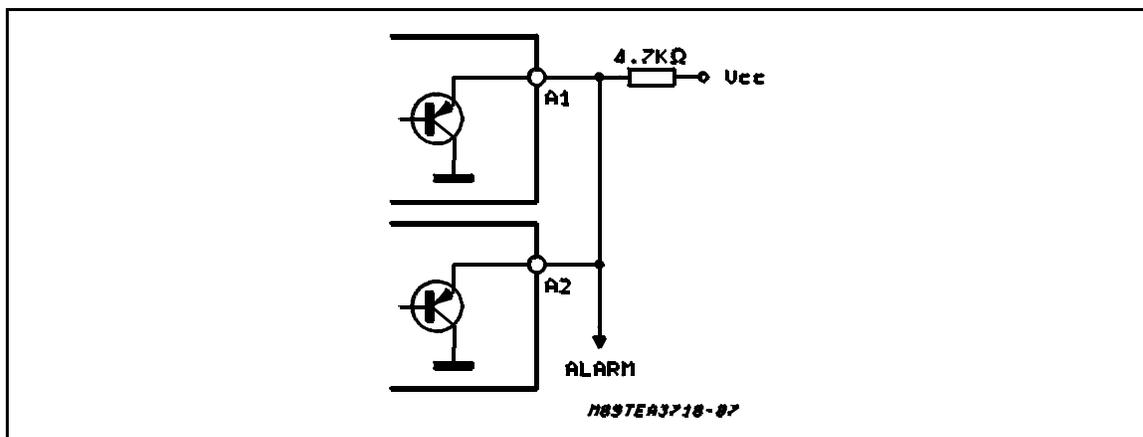

PRE-ALARM OUTPUT
When the junction temperature reaches T1°C (typ. = 170°C) a prealarm signal is generated.

Soft thermal protection occours when function temperature reaches T2 (T2 > T1)
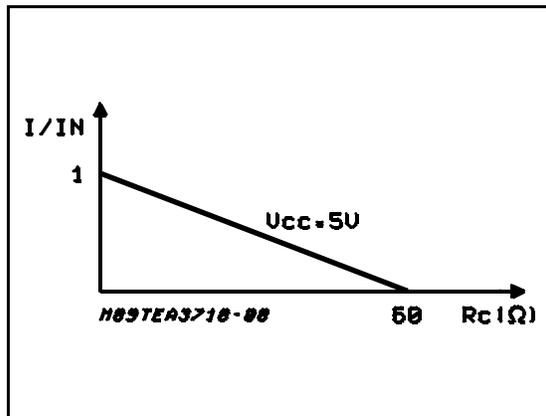

Figure C: Alarm Detection for Powerdip Package
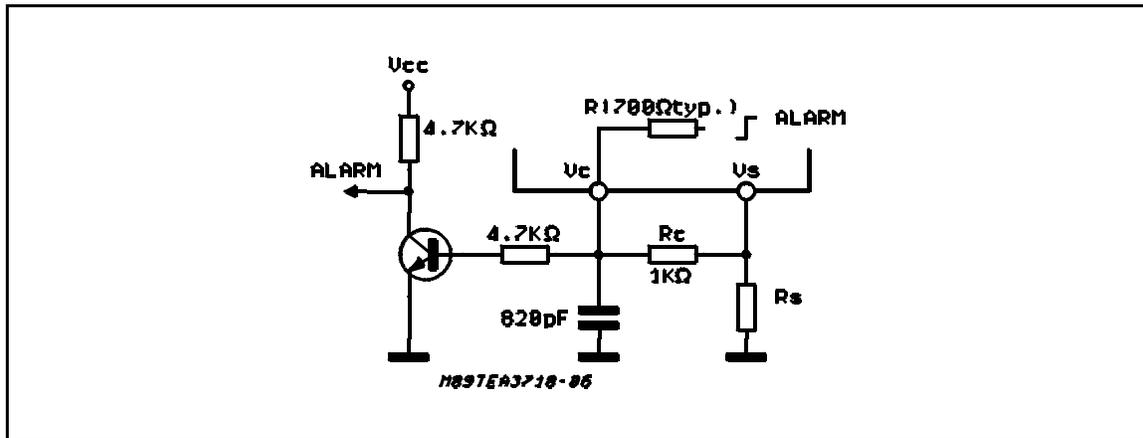

**Figure D:** CommonDetection for Several Multiwatt Package

Figure E: (typical curve) Current Reduction in the Motor on Alarm Condition.

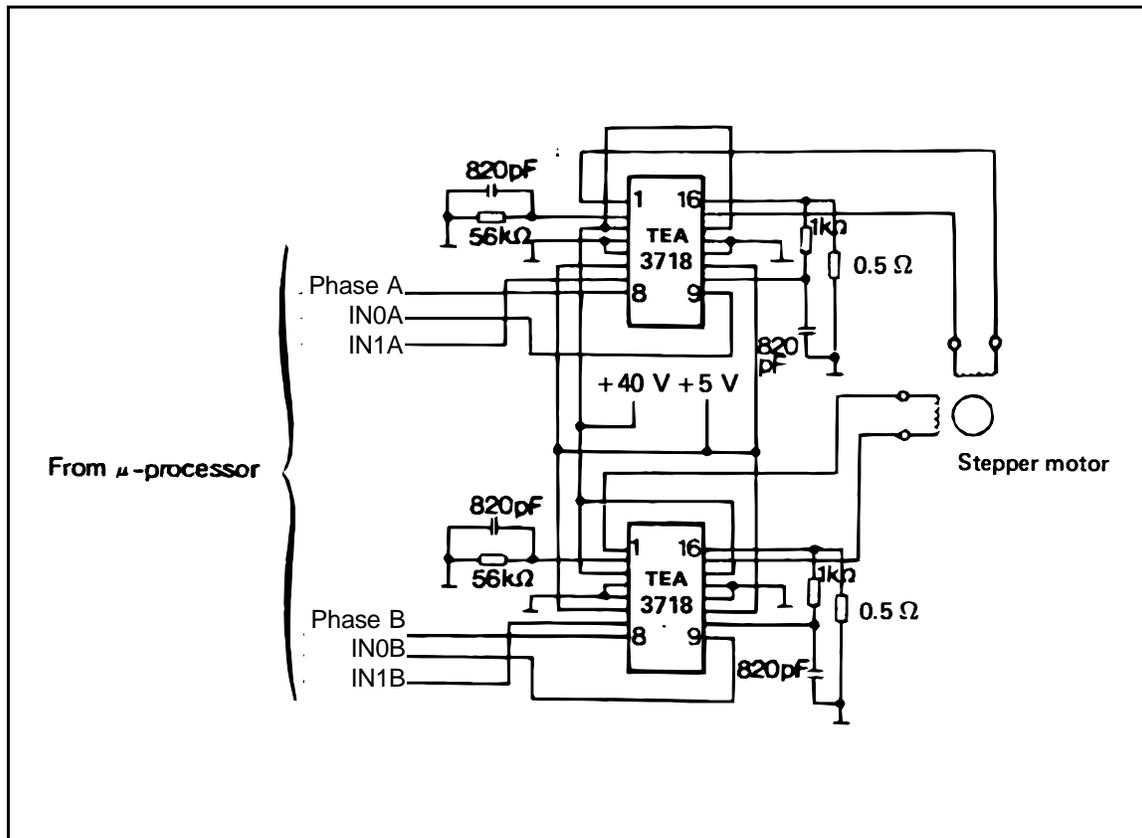

Figure F: (V_ref 5V) Block Diagram for Half Current on Alarm Condition.

Notes: 1. Resistance values given here are for the V_{ch} threshold. They should be adjusted using other comparators threshold or other V_{ref} value.

TYPICAL APPLICATION

FUNCTIONAL DESCRIPTION

The circuit is intended to drive a bipolar constant current through one motor winding. The constant current is generated through switch mode regulation.

There is a choice of three different current levels with the two logic inputs IN0 and IN1. The current can also be switched off completely.

INPUT LOGIC

If any of the logic inputs is left open, the circuit will treat it as a high level input.

IN0	IN1	Current Level
H	H	No Current
L	H	Low Current
H	L	Medium Current
L	L	Maximum Current

PHASE - This input determines the direction of current flow in the winding, depending on the motor connections. The signal is fed through a Schmidt-trigger for noise immunity, and through a time delay in order to guarantee that no short-circuit occurs in the output stage during phase-shift. High level on the PHASE input causes the motor current flow from Out A through the winding to Out B.

I_{H0} and I_{H1} - The current level in the motor winding is selected with these inputs. The values of the different current levels are determined by the reference voltage V_R together with the value of the sensing resistor R_S.

CURRENT SENSOR

This part contains a current sensing resistor (R_S), a low pass filter (R_C, C_C) and three comparators. Only one comparator is active at a time. It is activated by the input logic according to the current level chosen with signals IN0 and IN1. The motor current flows through the sensing resistor R_S. When the current has increased so that the voltage across R_S becomes higher than the reference voltage on the other comparator input, the comparator output goes high, which triggers the pulse generator and its output goes high during a fixed pulse time (t_{off}), thus switching off the power feed to the motor winding, and causing the motor current to decrease during t_{off}.

SINGLE-PULSE GENERATOR

The pulse generator is a monostable triggered on the positive going edge of the comparator output. The monostable output is high during the pulse time, t_{off}, which is determined by the timing components R_t and C_t.

$$t_{off} = 0.69 \cdot R_t \, C_t$$

The single pulse switches off the power feed to the motor winding, causing the winding current to decrease during t_{off}.

If a new trigger signal should occur during t_{off}, it is ignored.

OUTPUT STAGE

The output stage contains four Darlington transistors and four diodes, connected in an H-bridge. The two sinking transistors are used to switch the power supplied to the motor winding, thus driving a constant current through the winding.

It should be noted however, that it is not permitted to short circuit the outputs.

V_{SS}, V_S, V_R

The circuit will stand any order of turn-on or turn-off the supply voltages V_{SS} and V_S. Normal dV/dt values are then assumed.
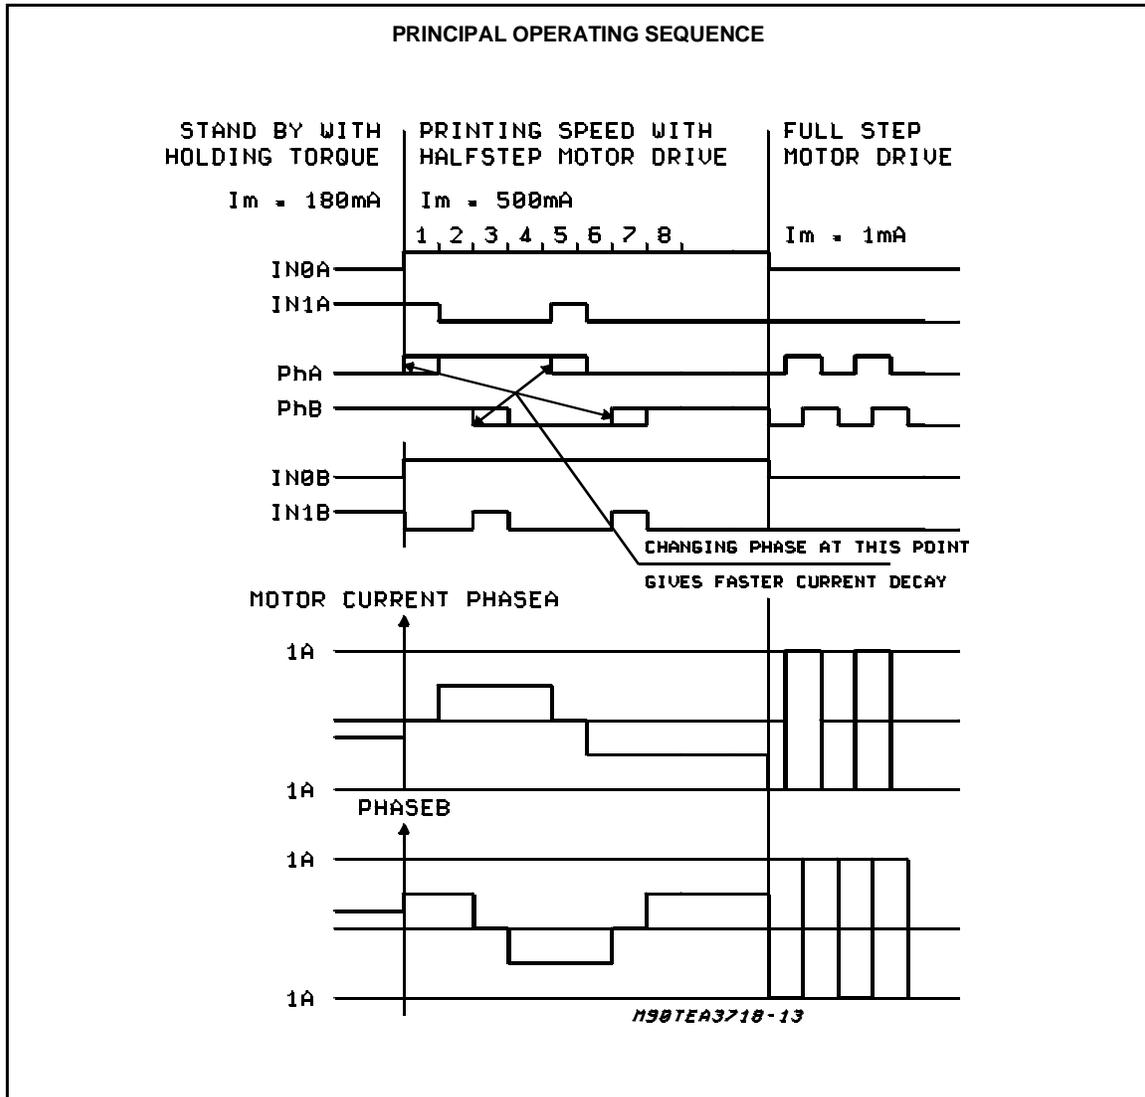

Preferably, V_R should be tracking V_{SS} during power-on and power-off if V_S is established.

ANALOG CONTROL

The current levels can be varied continuously if V_R is varied with a circuit varying the voltage on the comparator terminal.

POWER LOSSES V$_S$ OUTPUT CURRENT

PRINCIPAL OPERATING SEQUENCE

M98TEA3718-13
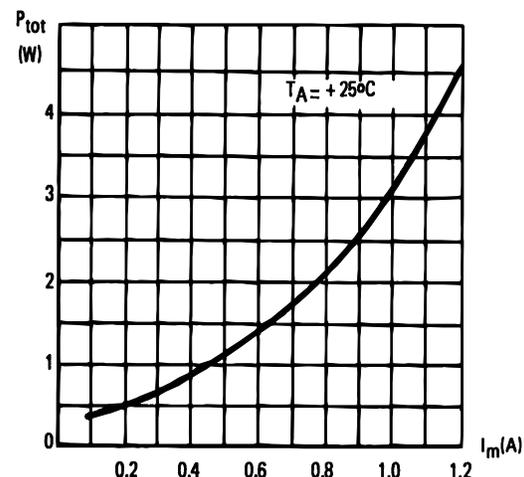

APPLICATION NOTES

MOTOR SELECTION

Some stepper motors are not designed for continuous operation at maximum current. As the circuit drives a constant current through the motor, its temperature might increase exceedingly both at low and high speed operation.

Also, some stepper motors have such high core losses that they are not suited for switch mode current regulation.

UNUSED INPUTS

Unused inputs should be connected to proper voltage levels in order to get the highest noise immunity.

### INTERFERENCE

As the circuit operates with switch mode current regulation, interference generation problems might arise in some applications. A good measure might then be to decouple the circuit with a 15 nF ceramic capacitor, located near the package between power line V_S and ground.

The ground lead between R_S, C_C and circuit GND should be kept as short as possible. This applies also to the lead between the sensing resistor R_S and point S, see FUNCTIONAL BLOCKS.
