## POWER TRIODE

- \* Because the cathode is subjected to considerable back bombardment as the frequency is increased with resultant increase in temperature, the heater voltage should be reduced depending on operating conditions and frequency to prevent overheating the cathode and resultant short life.
- § Without external shield.
- With external flat shield 7-1/2" min. diameter located in plane of the grid terminal and perpendicular to axis of tube. Shield is connected to grid terminal.
- Continuous Commercial Service.
- Computed between half-power points and based on tube output capacitance only.
- ✚ The driver stage is required to supply tube losses, rf-circuit losses, and rf power added to plate input. The driver stage should be designed to provide an excess of power above the indicated value to take care of variations in line voltage, in components, in initial tube characteristics, and in tube characteristics during life.
- # This value includes 24 watts of circuit loss and 36 watts added to plate input.
- This value of useful power is measured at load of output circuit having indicated efficiency.
- ⊕ This value includes 28 watts of circuit loss and 40 watts added to plate input.
- In cathode-drive, plate-modulated class C rf power amplifier service, the 6161 can be modulated 100% if the rf driver stage is also modulated 100% simultaneously. Care should be taken to insure that the driver-modulation and amplifier-modulation voltages are exactly in phase.
- \*\* This value includes 18 watts of circuit loss and 40 watts added to plate input.
- ⊕ This value includes 23 watts of circuit loss and 40 watts added to plate input.
- Key-down conditions per tube without amplitude modulation. Modulation essentially negative may be used if the positive peak of the audio-frequency envelope does not exceed 115% of the carrier conditions.
- ▲ This value includes 18 watts of circuit loss and 45 watts added to plate input.
- † This value includes 23 watts of circuit loss and 45 watts added to plate input.

### OPERATING CONSIDERATIONS

In tuning a cathode-drive rf amplifier, it must be remembered that variations in the load on the output stage will produce corresponding variations in the load on the driving stage. This effect will be noticed by the simultaneous increase in plate currents of both the output and driving stages.

During standby periods of less than 15 minutes, it is recommended that the heater voltage be reduced to 80% of normal to conserve life; for longer standby periods, the heater power should be turned off.
