Western Electric

275A Vacuum Tube

Classification—Moderate-power, filamentary triode

The 275A tube is designed for a maximum plate voltage of 300 volts.

Application—Audio-frequency amplifier where power outputs of about 3 watts per tube are required.

Dimensions—Dimensions, outline diagrams of the tube and base, and the arrangement of the electrode connections to the base terminals are shown in Figures 1 and 2.

Base-Medium, four-pin, thrust type with bayonet pin.

Socket-Standard, four-contact type, such as the Western Electric 143B socket.

Mounting Positions—Either vertical or horizontal. If mounted in a horizontal position, the plane of the filament, which is indicated in Figure 2, should be vertical.

Average Direct Interelectrode Capacitances

| Grid to plate | $12.0 \mu \mu f$. |
|-------------------|--------------------|
| Grid to filament | 6.8 μμf. |
| Plate to filament | 3.2 uuf. |

Filament Rating

| Filament voltage | 5.0 volts, a.c. or d.c. |
|--------------------------|-------------------------|
| Nominal filament current | 1.2 amperes |

The filament of this tube is designed to operate on a voltage basis and should be operated at as near the rated voltage as is practicable. When the filament is heated by alternating current, the grid and plate returns should be connected to a center tap on the secondary of the filament transformer.

Characteristics—Plate current characteristics of a typical 275A tube are shown in Figure 3 as functions of grid bias for several values of plate voltage. Similar characteristics as functions of plate voltage for several values of grid bias are given in Figure 4. Amplification factor, plate resistance, and transconductance characteristics corresponding to the plate current characteristics of Figure 3 are given in Figures 5, 6 and 7, respectively. All of these characteristics are for direct-current filament supply with the grid and plate returns connected to the negative end of the filament. For alternating-current filament supply, the same characteristics are applicable if approximately 3.5 is added to the numerical value of each grid bias.

Limiting Conditions for Safe Operation

| Maximum plate voltage | 300 volts |
|--|-----------------|
| Maximum plate dissipation | 17 watts |
| Maximum plate current of average tube for fixed grid bias | |
| Maximum plate current for manually adjusted grid bias or self- | • |
| biasing circuit | 80 milliamperes |

Operating Conditions and Output—Permissible combinations of operating plate voltage and plate current are included within the area, ABCDE, in Figure 3. Amplification factor, plate resistance, transconductance, and performance data are listed in the table below for typical operating conditions represented by selected points within this area. A less severe operating condition should be selected in preference to a maximum operating condition wherever possible. The life of the tube at maximum conditions may be shorter than at less severe conditions.

Where it is necessary to operate a 275A tube at or near its maximum operating plate current of 80 milliamperes or plate dissipation of 17 watts, provision should be made for adjusting the grid bias of each tube independently, so that the maximum safe plate current and dissipation will not be exceeded in any tube. Alternatively, a self-biasing circuit may be used, in which the grid bias for each tube is obtained from the voltage drop produced by the plate current flowing through a resistance. Where it is necessary to use a fixed grid bias, the plate current of the average tube should be limited to 70 milliamperes and its plate dissipation to 15 watts so that tubes having plate currents higher than the average will not exceed the maximum ratings.

The performance data include the fundamental power output and the second and third harmonic levels for the indicated values of load resistance and input voltage. The power output, P_m , is given in watts and the second and third harmonic levels, F_{2m} and F_{3m} , are given in decibels below the fundamental in each case. The peak value of the sinusoidal input voltage, E_{gm} , is numerically equal to the grid bias for each operating condition. For a smaller input voltage, E_g , the output and harmonic levels are given approximately by the following relations:

$$P = P_{m} \left(\frac{E_{g}}{E_{gm}}\right)^{2}$$

$$F_{2} = F_{2m} + 20 \log_{10} \frac{E_{gm}}{E_{g}}$$

$$F_{3} = F_{3m} + 40 \log_{10} \frac{E_{gm}}{E_{g}}$$

The variations of power output and harmonic levels with load resistance for several values of operating plate current are shown in Figures 8, 9 and 10 for a plate voltage of 250 volts. The sharp minima which appear in the third harmonic curves are characteristic of the 275A tube, but their positions may be different for different tubes. For this reason, the third harmonic level in any individual tube may be widely different from the value given in the table, where the operating condition under consideration is near one of these minima. Near these points, also, the expression given above for third harmonic level is not reliable.
