

sity greater than that of granite, as well as a strong cohesive force between its parts, in order to withstand the tendency to disintegration during its perihelion passage. Had the nucleus been either liquid or gaseous, or even a cluster of solid meteorites, the difference between the sun's attraction on the central and the superficial parts would have pulled the comet asunder, spreading out the fragments into somewhat different orbits, like the meteoric streams of August and November.—*The Analyst*.

LETTERS TO THE EDITOR.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. No notice is taken of anonymous communications.]

To the Editor of "SCIENCE."

I have much pleasure in enclosing you a copy of the particulars respecting the formation of our "Field Club," which I believe to be the third in England of similar pretensions, its original founders being Mr. Thomas Kiddie and myself, both being science students, and by profession analysts in manufactories on Coaly Tyne. We were at first inclined to restrict the Club to those of our own class, namely, Students in Chemistry, but knowing the intimate connection between all the other branches of Science and that of Chemistry, we determined to throw it open to all science students, and we are now pleased to find that our efforts have had such a successful issue so far, and met with such general approval throughout the whole district, as we have at present, after two months establishment, about 100 members, some living as far as fourteen miles from our centre; also having the countenance of fourteen gentlemen interested in scientific education as honorary members. The officers consist of students or teachers (under the Science and Art Department, London). Should you consider our club worthy a comment in your excellent journal, which latter must act as a valuable adjunct to the aims of scientific education, I shall be exceedingly obliged if you will forward me a copy to read at one of our excursions.

M. THEODORE DIXON, *Hon. Sec.*
5 BRANDLING PARK, Newcastle-on-Tyne, Eng.

[We print the above letter in the hope that it may suggest the formation of Field Clubs in the United States. The value of such organizations cannot be overrated, and we shall be glad to hear that some of our subscribers have taken the initiative in such an agreeable enterprise. We shall send information to those who desire it.—ED.]

CHEMICAL NOTES.

THE MARQUIS TOMMASSI has succeeded in sending a message across the Atlantic with two Minotto elements.

AN APPLICATION OF ACCIDENTAL IMAGES.—J. Plateau, from some experiments performed by his son, concludes that the *apparent* distance of the full moon is only 50 metres from the observer.

PROPAGATION OF LIGHT.—M. Gouy has shown that there is not, for a given homogeneous source, a determined speed of light independent of the manner in which the amplitude is caused to vary.

PHYLLXERA IN FRANCE.—It appears that more than a third part of the vines in France have been already destroyed by the phylloxera. The departments of Haute Savoie and Jura are now attacked.

SPONTANEOUS OXIDATION OF MERCURY AND OF METALS.—Mercury, as well as iron, zinc, cadmium, lead, copper, and tin, undergoes on exposure to the air a superficial oxidation, very slight, and restricted by the difficulty of renewing the surfaces and by the want of contact which results

from the layer of oxide formed at the outset. For the oxidation to continue this layer must be constantly removed, as in the case with rust of iron formed in moist air, or for each hydrocarbonate produced in distilled water.—M. BERTHELOT.

WINES MIXED WITH GRAPE SUGAR.—The non-fermentable part of the grape sugar which is introduced into wines, if administered to dogs by way of subcutaneous injection produced vomiting and other morbid symptoms. A. Schmitz claims that these residues contain a poison similar to that present in potato-oil.

ACTION OF PHOSPHOROUS UPON HYDRIODIC AND HYDROBROMIC ACIDS.—With hydriodic acid and white phosphorous the latter melts and becomes covered with a reddish layer of biniiodide, while phosphonium iodide sublimes. With red phosphorous even at 100°, there is produced merely a small quantity of phosphonium iodide. Upon dissolved hydrobromide acid, phosphorus does not react in the cold. At from 100° to 120°, phosphonium bromide sublimes, but no phosphorous bromide is produced.—A. DAMISEAU.

THE SOCIÉTÉ D'ENCOURAGEMENT POUR L'INDUSTRIE NATIONALE has awarded the Le Blanc prize of 1000 francs for the utilization of manufacturing refuse to M. Vincent, for his process for obtaining methyl chloride from the *vinasses* of the beet-root sugar manufacture. A sum of 1000 francs has also been awarded to M. J. A. Martin for his mixtures for rendering textile articles, paper, &c., unflammable. His ordinary mixture for light goods is: Pure ammonium sulphate, 8 kilos; ammonium carbonate, 2 kilos, (5); boric acid, 3; pure borax, 2; starch 2 (for which may be substituted 0.400 kilo. dextrine, or the same weight of gelatine), and water 100 kilos. A silver medal has been awarded to M. Idrac for his process of drying timber.

A NEW ELECTRIC PROPERTY OF SELENIUM, AND THE EXISTENCE OF TRIBE-ELECTRIC CURRENTS PROPERLY SO CALLED.—R. Blondlot has observed a new electric property of selenium which may be shown by the following experiment: To one of the poles of a capillary electrometer there is attached, by means of a platinum wire, a fragment of selenium which has been recently heated, and to the other pole a platinum foil. If the selenium is brought in contact with the platinum, holding it by means of an isolating handle, the electrometer remains at zero, as might be expected from the symmetry of the circuit; but if the selenium is rubbed against the surface of the metal the electrometer deviates strongly, the deviation obtained being equal to that produced by a sulphate of copper element.

ANALYSIS OF SUPERPHOSPHATES.—In acting upon a superphosphate made of bone-black or from the phosphate of Caceres with a solution of ammonium citrate of sp. gr. 1.09, there is no occasion to take into account the time of action or the fluctuations in the temperature of the laboratory. In the analyses of a bone-black superphosphate, an excess of citrate must be avoided—20 c.c. are sufficient for 2 grms. of the sample. An excess of the reagent dissolves part of the phosphoric acid of such tricalcic phosphate as has escaped the action of sulphuric acid in the manufacture of the superphosphate. The phosphate of Caceres is much less sensitive to the action of the citrate than the phosphate of bone-black, and here from 20 to 100 c.c. may be taken to 2 grms. of the sample.—L. CHEVRON.

DETERMINATION OF CHICORY IN GROUND COFFEE.—M. Prunier suggests the following method: Two grms. are weighed out and separated from the finer powder by sifting through fine silk. This powder which, as microscopic examination proves, is composed entirely of pure coffee, is set aside. That which remains on the sieve is macerated with a few grms. of water in a test glass. After some hours it is thrown upon a piece of cloth stretched out and crushed with the fingers. The grains of coffee resist the pressure, whilst those of chicory, reduced to a paste by soaking in water, penetrate into the cloth and adhere to it. On drying the cloth it is easy to detach the coffee, which, after dessication at 100° and addition of the fine powder separated at first, gives the weight of pure coffee. The chicory is calculated as loss.
