

wrote these down word for word from the lips of the narrators in their native tongue, and at his leisure afterwards translated them into English. Some of them were obtained by the distinguished folk-lorist and poet, Charles G. Leland, and published in his "Algonquin Legends." A much larger collection of them, filling a volume of 452 pages, has just appeared in the Wellesley College Philological Publications, entitled "Legends of the Micmacs," with a most satisfactory preface by Miss Helen L. Webster. It is a work the reading of which is both delightful and instructive, and it leads us far into the psychology of these children of nature. The original Micmac of most of these tales is still in existence, and should some day be printed for its linguistic value.

PLEA FOR TEACHING THE HISTORY OF MATHEMATICS.

BY JOSEPH V. COLLINS, PH.D., WOOSTER, OHIO.

THE time allotted in our schools for the study of political and general history, as is well known, is all too short. Doubtless many teachers on seeing the title above would be disposed to say that it is well enough, but how can the teacher of mathematics find time for it? And, besides, if a little history is a good thing in the mathematics, why would it not be equally desirable in language and science? A fair answer to the latter question presents itself, viz.: Perhaps it would.

It is not surprising that the history of mathematics is neglected in the common schools, because the normal and training schools do not concern themselves with it. The latter have some excuse for this course, since the colleges, from whence they draw their teachers, either pay no attention to it, or only the scantiest, and that indirectly. It is fair to suppose that in a large number of cases the college student of to-day gets his knowledge of Greek mathematics, not from the mathematical department, but out of his Greek studies, and in a crude and confused form. He knows, or, of course, ought to know, that the elementary geometries in use now are merely Euclid's in substance, superior to Euclid's in some ways, but in others less logical. If he were asked to describe the Greek mathematics, or to tell when algebra was first cultivated, it is doubtful whether he could give any satisfactory answer. Indeed, some very interesting statistics could no doubt be secured if these and a few other like questions were put to the seniors in our various colleges. It is doubtful whether the majority would know whether algebra was studied first in the fourth or fourteenth century, or whether trigonometry was cultivated for its own sake at first or as an auxiliary to another science, and if the latter, what science? That effect, whether great or small, the invention of cartesian co-ordinates had on the development of geometry? Whether our present notation in algebra was fixed by a few or by many hands? Or the answers to numerous questions as important as these. Those who had traversed the ground of a good history, besides securing a much clearer comprehension of subjects they had taken years to learn, would have become acquainted with the evolution of a branch of science from humble beginnings and with slow steps, and indirectly would have had a good sidelight thrown on general history.

Even in our universities, if one may judge by the courses set forth in their catalogues, there is no distinct provision or requirement to secure a knowledge of the history of mathematics, and so it would seem just to charge neglect of the historical and unifying side of the study of mathematics all along the line of our educational system. Of course there are exceptions to this. Cajori in his "History and Teaching of Mathematics in the United States" (page 163) says:

"One feature of the mathematical instruction at this institution [Princeton] that has been in vogue during the last ten years (perhaps longer) is, we think, to be recommended for more general adoption. Considerable attention is given to the study of the history of mathematics. The writer has before him examination papers, written in answer to questions set by Halsted in 1881. From the answers we infer that questions like these were asked: Who wrote the first algebra that has come down to us? What was its nature? What part did the Hindoos play in the development of algebra? Its growth during the Renaissance? The laws underlying ordinary algebra? etc." The same book gives the following in the mathematical courses in the University of Texas, where Professor Halsted now is: "In the higher classes will be discussed the history and logical structure of the mathematical sciences." Lectures on the history of mathematics are given also at the University of Virginia. No doubt other instances might be found of historical courses offered, but on the whole this is the exception. It seems scarcely necessary to criticise this condition of affairs, as I presume almost anyone would agree that it is unfortunate. It is likely that it is due to the fact that each professor is a specialist and is unwilling to take from his own work the time necessary to prepare such a general course.

The present seems an opportune time to bring forward the claims of this special study, since a new history of mathematics by an American author (Professor Cajori) is soon to appear from the press of Macmillan & Co. So far as the writer knows, it will be the first of its kind to be brought out in this country. It is to be hoped that if the book proves worthy, which it no doubt will, it will have a large sale among college professors, and also among teachers of more elementary mathematics. It will be a mistake for the latter to conclude that they can make no use of such a book. For along with enlarging their views of mathematics, they will find many facts of interest, many old principles new to them, some ideas of prime importance for the proper teaching of scientific geometry, algebra, trigonometry, and analytics, and much material—some stories, perhaps—that may be used to break the monotony of class-room routine. A teacher who does not know what was the controlling idea in the Greek geometry, or one who has never appreciated the difficulty met with in the study of incommensurables, or in attaining a satisfactory theory of parallels, is hardly in position to teach elementary geometry as it should be taught. Many of the results of mathematics, dry and abstract though they may seem from one standpoint, are yet full of interest when viewed as a part of the development of the subject, or when the circumstances under which they were discovered are known. Sometimes a knowledge of the personality of an author of a work, or a demonstration or problem, adds interest to its study. The stories concerning the legend over Plato's door, Archimedes and the Roman soldier, and Newton's apple, are not the only ones that may be related even of these men,—may their shades forgive us for having harped on them so long,—for one and perhaps two of them are apocryphal. But one of the best results of a study of this history by the teachers of elementary mathematics would be the enlarging of their mathematical horizon. Too many even at the present time think that the mathematics that lies beyond a knowledge of the elements of the calculus as set forth in our ordinary college courses is of a transcendental and non-useful character. It is safe to say that by as much as a teacher's vision is widened and clarified, by that much is he made a more intelligent and capable instructor. We enter a plea therefore for a better knowledge of the history of mathematics, hoping thereby to secure a better knowledge and teaching of the subject itself.
