

Recognizable organic remains have been found by Walcott⁴ in a small, isolated area of lower Cambrian rocks at the base of the Sierra west of Big Pine, in Inyo County, and provisional Triassic forms from the roof pendant at Mineral King have been noted by Turner.⁵ As yet, no report of fossils from any part of the escarpment between Big Pine and Mono Lake has been seen by the writer. For this reason, it may be of interest to record the recent finding of probable mid-Devonian fossils in crystalline limestone (marble) on the Sierra Nevada escarpment, about 28 miles south of Mono Lake, by Mr. W. E. Selbie, a prospector. The writer has spent three summers in geologic field work in this region, part of which was done under the auspices of the California State Division of Mines, and supervised by Dr. Olaf P. Jenkins, chief geologist. On various occasions during the investigation, Mr. Selbie rendered valuable assistance. He became interested in the progress of the work, and in the possibility of finding fossils in the older rocks.

A few months ago, Mr. Selbie sent to the Geology Department at Cornell University, a package containing two fossils, one a large crinoid stem (.4 inch in diameter), and the other a small brachiopod. These remains are stated by him to have been found in a bed of crystalline limestone, which outcrops on a mountain side a few hundred yards east of Laurel Creek, in southwestern Mono County. They were examined at Cornell University by Professor G. D. Harris, who states that the age of the fossils is uncertain, but they somewhat resemble mid-Devonian forms. The brachiopod is thought to be near *Leiorhynchus* sp. (?).

There can be little doubt that the Paleozoic rocks along the escarpment range in age from lower Cambrian to Devonian. Whether or not the whole of the Paleozoic section is represented remains uncertain. It is hoped that future investigation will yield further data to confirm those now at hand, and to enable further conclusions to be made. The finding of more fossils, over a wider area, would not only make it possible to recognize the formations present, but would offer a valuable check on interpretations of geologic structures in the older rocks.

NAMING DISORDERS OF SPEECH

REALIZING the need of a systematic international classification of disorders of speech and voice, the American Society for the Study of Disorders of Speech appointed a nomenclature committee three

years ago to prepare such a classification. The committee felt that such a classification should not be published in entirety, however, until accurate definitions of every disorder of speech listed had been approved by at least the leaders in the field of speech correction.

In order to give all workers in this new field of science an opportunity to criticize the best definitions the committee were able to obtain, the committee has just published a tentative "Dictionary of Terms Dealing with Disorders of Speech," and requests those interested to revise every definition which does not adequately describe a given disorder of speech as they have actually known it, and to send the revision to the committee. Only so can an accurate revised edition of this dictionary accompany the publication of the final international classification of disorders of speech and of voice.

SECRETARY AND CHAIRMAN OF
NOMENCLATURE COMMITTEE

A CURIOUS FISH STORY

A QUITE curious case of gastric erosion of a fishhook that had been swallowed by a fish has come under my observation. Many experienced fishermen tell me that they have seen nothing quite like it. At about eight o'clock in the evening of July 1, Professor C. E. Hagie, of the History Department of Western State College, hooked a twelve-inch Loch Leven trout while fishing on the Gunnison River. When this fish was cleaned it was discovered that it had at some previous time swallowed a No. 2 Carlisle bait hook. The barb of this hook had penetrated the wall of the stomach and all of the curvature of the hook to a point on a level with the tip of the barb lay in the body cavity. The straight shank of the hook lay entirely in the stomach. Outside of the stomach the hook was in good condition; inside the stomach it had been so eroded by the gastric action that but a mere filament of the former metal was left.

An interesting question as to how long it may take for such erosion to be brought about presents itself. According to the best opinion that I can get at the hands of expert fishermen of long standing, a twelve-inch trout, in the Gunnison River, takes about three years to reach this size. Trout are put into the river as fingerlings. They grow rapidly and, in a year, according to food conditions, reach a length of about seven inches. In another year they reach a length of from eight to ten inches. The third year they may reach a length of twelve inches.

It would seem certain that the amount of erosion of the fishhook in the stomach of the fish in question would preclude the possibility of its having been swallowed during the present fishing season. This
