

Meetings

Statistics and Probability

During the week of 2-8 March, an international conference on statistics and probability took place in the Mathematical Research Institute, Lorenzenhof, Oberwolfach, Germany. This conference exhibited the remarkable growth of interest in statistics on the continent of Europe. Also it emphasized a certain shift in emphasis in statistical research in general. For these reasons, a brief account of the conference may be of general interest.

As is well known, up to the end of World War II, the geographical location of research in statistics and in probability was extremely uneven. Statistical theory (that is, theories of tests of hypotheses, of estimation, and of decision functions) was developed mostly in English-speaking countries and was largely ignored in western Europe. Probability theory centered in France and in Russia, while English-speaking countries trailed behind. After the end of the war, this situation changed radically. The works of Bochner, Doob, Feller, and Loève brought this country to the forefront of probabilistic research, and, at the same time, there appeared in Europe several

young centers of research in statistics which promise remarkable developments. In addition to this geographical redistribution of effort, the end of the war marked a change in the subject of statistical research which may justify a distinction between what may be called the classical and the modern theories of statistics. I propose to use the term *classical* to describe those sections of statistical theory that deal with *numerical* random variables. They may be exemplified (i) by measurements, subject to random error, of a given physical magnitude; (ii) by responses to a treatment of organisms selected at random from their population; (iii) by pairs of numbers of ions generated by a cosmic ray particle in two adjoining unit lengths of its path; and so on. In each of these cases we deal with a chance mechanism producing *numbers*, either singly or in pairs or in multiple groups. More recently, modern science and modern industry brought under consideration more complicated chance mechanisms, connected with the term *stochastic processes*, which, at a single trial, produce not just a single number or a finite set of numbers but more complicated mathematical entities, such as a function. In the classification proposed, the term *modern theory of statistics* is applied to the statistical theory relating to stochastic processes—that is,

to random variables whose possible values are not numbers but functions.

The basis for this subdivision of statistical problems into the categories “classical” and “modern” is the difference in the mathematical apparatus needed for their treatment. Consider a classical problem of statistics with some n observable numerical random variables X_1, X_2, \dots, X_n . The possible values of each X_i are numbers. Hence, if one visualizes the n -dimensional Euclidean space, a single observation on these variables can be represented by a single “point” with its first coordinate equal to X_1 , its second coordinate equal to X_2 , and so on. The probability that the random point (X_1, X_2, \dots, X_n) will fall within any specified region, say R , is then represented by the measure of this region. The theory of measure is based on the works of Borel and Lebesgue, developed early in this century and now commonly taught in all universities with reasonably developed mathematical programs. The situation is different with modern statistical problems in which the outcome of a single “trial” is a curve, say $f(x)$ for values of x between zero and unity. If one tries to extend to this case the representation of the outcome of a trial by a point, it is necessary to deal, roughly speaking, with as many coordinates as there are numbers between zero and unity—that is, the continuum. For “spaces” filled with points of this kind (“abstract spaces”), one needs a definition of “distance,” of “measure,” and so forth. Theories of these concepts (Hilbert spaces, Banach spaces, and so on) are of more recent origin and are included in our university programs only in the most advanced institutions.

As far as “modern” problems are concerned, it was logical and unavoidable that their probabilistic treatment should precede their statistical treatment. The priority here belongs to the Russian school of Kolmogorov and Khintchine. More recently, the remarkable book by Doob clarified many concepts and cleared new paths. While it is difficult to point out exactly the first attempts at statistical problems concerned with stochastic processes, we certainly owe a great deal to the Scandinavian school of Cramér, particularly to Grenander. However, modern statistical theory is still in its infancy. One reason for this state of affairs is the tendency of statisticians to concern themselves with the so-called “practical” problems suggested by various fields of application, and, until recently, both science and industry offered only problems with numerical random variables. However, currently one encounters a number of problems where the observable random variables are curves. One example must suffice. The “observations” by a radio telescope provide a single oscillating curve summariz-

ing the radio emissions of all the sources located within a certain solid angle. Cosmological theories are concerned with the spatial distribution of these sources (one particular chance mechanism) and with the distribution of their individual intensities (another chance mechanism). Also, the records of emission of the cosmic radio sources are combined by the telescope with unavoidable "noise" (a third chance mechanism). The statistical problem here is to use the observable random curve in order to verify this or that cosmological theory. Modern industry provides similar problems. Thus, the domain of probability distributions in abstract spaces that, until recently, was frequently considered one of the dreams of abstract-minded pure mathematicians, is now rapidly becoming a domain of practical statistical problems. In order to stand up to these practical demands, the efforts of theoretical statisticians must be reoriented.

The conference in Lorenzenhof reflected both of the changes indicated: the change in the geographical distribution of effort in statistical research and the change from classical to modern statistical problems. Of the 42 participants, 32 were from Germany and ten were from other countries (three from the United States and one each from Austria, Czechoslovakia, Egypt, Finland, France, Holland, and Hungary). Each of the foreign visitors and nine Germans were asked to present papers. The contents of these papers are far too technical to be reported here, and the following brief enumeration is limited to cases where the contributions at the conference indicated the emergence of a new statistical research center on the continent of Europe. There appear to be at least five such centers, each inspired by an outstanding personality. Roughly, from West to East, these centers are Paris, Hamburg, Munich, Prague, and Budapest.

For quite some time Paris has been one of the foremost centers of research in probability. However, the theory of statistics seemed to attract less attention. Now this situation has changed, and the conferences at Lorenzenhof were much impressed by a very interesting statistical paper by Robert Fortet, a noted probabilist. This paper dealt with the theory of testing statistical hypotheses concerned with stochastic processes and established an intriguing connection with Shannon's theory of information.

Hamburg was represented by L. Schmetterer, leader of the group; by the recently appointed docent, Krickeberg; and by a group of promising graduate students. Incidentally, Schmetterer was responsible for the organization of the scientific program of the conference at Lorenzenhof. His own paper was probabilistic and dealt with limit theorems on groups. Krickeberg spoke on convergence

MOST COMPACT ON MARKET!

Aminco-Lardy Warburg Apparatus

Cat. No. 5-140 Warburg, Aminco-Lardy—nine stations; equipped with bi-metal thermoregulator, but without manometers, supports and vessels which must be ordered separately.

The same excellence of design, workmanship and materials that are built into Aminco's other time-proven Warburg instruments for manometric research are now incorporated into its newest member of the family, the Bench Model Warburg Apparatus.

The overall diameter of 16 inches and total weight of 63 lbs. make this Warburg the smallest and lightest commercially-available instrument of its type on the market. It is especially useful where lab space is limited, and ideal for classroom instruction.

Nine manometer stations are provided to accommodate four pairs of operating manometers and one thermobarometer.

Designed to maintain close temperature control, the difference in temperature measured between any two points at an operational depth in the bath is less than 0.01°C.

Shaking of flasks is adjustable in both frequency and amplitude, and each manometer can be easily removed to provide accessibility to individual flasks without disturbing remaining samples.

Temperature range: Ambient to 50°C.
Power requirement: 115 v., 60-cycle, a-c.

of stochastic processes and exhibited signs of the influence of Doob.

The center of Munich provided four active participants, D. Bierlein, K. Jakobs, K. Gaede, and H. Richter. The first three spoke on problems of probability, while Richter dealt with Lindley's version of the statistical decision problem. The same problem was also treated by E. Brandau of Tübingen.

The two statistical groups of eastern Europe, one in Prague and the other in Budapest, were represented at the conference by their respective leaders, A. Spacek and A. Renyi. Their papers tes-

tified to the very intense and modern activity of the two groups and were loaded with material.

While several of the papers mentioned, and also some of those omitted from the above enumeration, were essentially probabilistic in character, they included distinct statistical elements. Also, predominantly, the papers presented dealt with modern problems.

Taking into account the activities of the new centers just described, together with those of the older centers in Holland, Denmark, Scandinavia, and Poland, all subject to a considerable extent

to influences of the Russian school, one obtains the impression of a very strong drive now prevalent in Europe towards the development of an important new chapter of statistical theory.

The present account would be incomplete without a few lines about the Mathematical Research Institute at Lorenzenhof. Erected in the hills of Schwarzwald early in this century, the Lorenzenhof was intended to serve as the hunting lodge of a magnate. In due course it became the property of the state and, in 1944, became the seat of the Mathematical Research Institute. Originally, the intention was to concentrate certain branches of war research in the institute. However, in practice, the Lorenzenhof became a refuge for some of the German mathematicians who, for various reasons, had to abandon their university positions. Currently, under the wise guidance of its director, W. Süss of Freiburg University, and of his colleague and friend, H. Kneser of Tübingen University, the activities of the institute consist of the organization of some 12 mathematical symposia per year. Each symposium is given to a separate mathematical discipline and lasts about a week. From time to time, individual mathematicians come to Lorenzenhof for a period of quiet work.

As a means for fostering research, the usefulness of the institute and of its symposia is supreme. Leisurely life in beautiful surroundings, divided between a moderate number of lectures, walks in the countryside, and occasional periods of good music, creates excellent opportunities for informal contacts and discussions which have a most beneficial influence on the development of mathematicians in Germany and, through a substantial attendance from abroad, also elsewhere. One cannot help asking: What about establishing a similar institution in the United States?

Hot Laboratories

Abstracts for papers to be presented at the seventh Conference on Hot Laboratories and Equipment, to be held in Cleveland, Ohio, April 1959, are due on 15 September 1958 and should be sent to the program chairman: L. G. Stang, Jr., Brookhaven National Laboratory, Upton, N.Y. Deadline for papers will be announced later. Papers are invited on all phases of hot laboratories and equipment for handling radioactive material, including design, construction, operation, maintenance, decontamination, remodeling, shielding calculations, costs, and so forth.

FISHER

ISOLATOR/LAB

*a complete
laboratory
in less than 7 sq. ft.
for hazardous and
purity-sensitive operations*

The Fisher Isolator/Lab is a compact, moderately-priced, self-contained laboratory within a laboratory. It has its own services, air supply and exhaust system.

The basic Isolator/Lab provides you with an isolating unit with scores of uses including: handling of toxic chemicals; bacteriological, radiologi-

cal and metallurgical procedures; sterile pharmaceutical dispensing and packaging; allergy studies; etc. Whatever the use, the operator is at all times protected against hazardous materials and the material itself is protected against contamination.

And—as your needs grow, a wide variety of accessories may be added.

First All-India Conference of Zoology

The Zoological Society of India is organizing the first All-India Congress of Zoology, to be held in Calcutta from 31 October to 6 November. This is the first time that an attempt has been made to bring together all the zoologists in India. A number of delegates from foreign countries are also expected to attend. Dr. B. S. Chauhan of the Zoological Survey of India, Calcutta, is the local secretary. The last date for submission of papers to be read before the congress is 15 August.

Erratum: The correct address for the Society for the Scientific Study of Sex is 1 E. 42 St., New York 17, N.Y. The society will hold its first meeting on 8 November at the Barbizon-Plaza Hotel in New York.

Letters

Withdrawal versus Withholding of Positive Reinforcement

C. B. Ferster (1) in his experiments used withholding of food reinforcement (called by him withdrawal of positive reinforcement) in differentiation of conditioned motor reflexes. It seems, however, that under the circumstances of his experiments, the procedure cannot be considered as "the withdrawal of positive reinforcement" nor as "the withdrawal of the situation in which the reinforcement occurs." The situation in which the reinforcement occurred was only partially changed by switching off of the overhead lamp, or by appearance of the red light, and in spite of the fact that the animal performed the movement (pressing of the key), the reinforcement was withheld. The differentiation which was attempted in these experiments developed slowly and was only a partial one, because the reinforcement was withheld regularly only when the movement occurred during periods when the red light appeared, whereas in the absence of the red light the reinforcement was applied irregularly.

Ferster emphasizes in his report the analogy between the punishment and the withholding of positive reinforcement, both of which had as a result the elimination of the conditioned movement. But I think that there is a very important difference between the two events: the punishment, whether used in classic conditioning (type I) or in escape or avoidance conditioning (type II) (2), can give rise to new conditioned movements, whereas the differential inhibition can only eliminate some preexisting conditioned movements. The suggestion that punishment and differentiation have common "aversive" features is, as of the present time, based only on introspective impressions.

In my own experiments (3), when real withdrawal of positive reinforcement was used, a new kind of behavior was obtained. These experiments consisted in the withdrawal of food during the act of eating. The withdrawal was signaled by an acoustic stimulus applied 5 to 10 seconds beforehand. After several such trials the animal stopped eating when the stimulus sounded and turned away from the food tray. This conditioned "cessation reflex" was later differentiated: the food was withdrawn after one of the stimuli, but after another it was not. During the action of the first stimulus the dog turned away from the food, but during the action of the other (that which was not reinforced by withdrawal of food), he ate without interruptions.

Thus, both the inhibition produced by

New G-E x-ray microscope...

multiplies penetration, resolution, magnification

New frontiers of research and development are being explored *today* with the General Electric x-ray microscope. Revealing internal structures invisible under conventional microscopy, this versatile instrument's high resolving power permits magnifications up to 1500 times.

Images can be viewed on a fluoroscopic screen, photographed directly on Polaroid® film, recorded on conventional film or presented in stereo for that important third dimension. Specimens do not have to be placed in a vacuum.

You can get complete information from your G-E x-ray representative. Or write X-Ray Department, General Electric Company, Milwaukee 1, Wisconsin, for Pub. SC-64.
