Oxygen Transport

I found Scholander's article on O_2 transport [*Science* 131, 585 (1960)] very interesting, and I think I can lend support to it since similar conclusions were drawn (though not published) by myself and J. P. Baumberger some years ago in a completely different experimental situation [*J. Gen. Physiol.* 36, 255 (1952)].

We found that the polarographic diffusion current for O_2 given by whole blood was six times greater than that given by plasma when both were measured at O_2 tension of 100 mm-Hg at 37°C. This excess diffusion current depends not only on red cell concentration but on factors which increase the rate of dissociation of HbO_2 : degree of O_2 saturation, pCO_2 , pH , and temperature. The readiness with which HbO_2 releases O_2 determines (i) the rate at which O_2 is replaced in the immediate vicinity of the "consuming" cathode and (ii) the rate at which Scholander's "bucket-brigade" operates, at a greater distance from the cathode. (The rate of "passing the bucket" obviously depends on the dissociation rate.) The driving force behind this steady-state flow is the constant rate of O_2 "consumption" of the cathode, which maintains a constant pO_2 gradient in its vicinity.

The resultant of this situation is that, at a pO_2 of 100 mm-Hg, the cathode receives O_2 from whole blood at a rate at which it could receive O_2 from plasma only at a pO_2 of 600 mm-Hg. If we now substitute rapidly metabolizing cells for the cathode, the conclusion follows that in the presence of oxygenated red blood cells the effective rate of diffusion of O_2 to the consuming cells at a given pO_2 will be much greater than could be expected on the basis of the O_2 tension difference alone.

Competitive Exclusion

As an economist, I have been delighted with the recent revival of the earlier view that ecology and economics are closely related. Hardin's article ["The competitive exclusion principle," *Science* 131, 1292 (29 Apr. 1960)] is an excellent example of this revival, as would be expected in view of his previous work. Unfortunately, it contains an error in economics. From the principle that complete competitors cannot coexist he deduces the develop-

ment of monopolies. The principle, however, applies to species, not individuals. Park's experiments did not show that one individual flour beetle grew so large that it eliminated all the others, only that one species grew so numerous that it eliminated the other. If the principle has any application to economics at all, it would indicate that one type of economic enterprise might, by multiplication of its members, replace another, but this would not lead to monopoly. The problem of monopoly is a real one, and an important one, but it has nothing to do with the competitive exclusion principle.

I rather dislike attacking an article which is, in general, as superior as Hardin's, but in this one area he is wrong.

GORDON TULLOCK

Department of International Studies,
University of South Carolina, Columbia

Garrett Hardin points out that the "competitive exclusion principle"—that is, that "complete competitors cannot coexist"—is essentially a theoretical concept unlikely of direct proof in the field. I believe this conclusion is strengthened if it is considered that at least three common conditions, not mentioned by Hardin, must be *absent* if the replacement of one species by its complete competitor is to proceed in a direct fashion. However, at least two of these conditions are likely to be *present* in the field unless the replacement process is quite rapid.

If there exist two complete competitors, species A and B; if species A is slowly replacing species B; and if this process is to continue directly to the point of (local) extinction of species B; then the following possibilities must *not* occur:

- 1) A decrease in the genetically determined competitive ability of species A below the level of that of species B.
- 2) An increase in the genetically determined competitive ability of species B above the level of that of species A.
- 3) A change in the environment sufficient to shift the competitive superiority from species A to species B.

The first possibility is somewhat unlikely, on evolutionary grounds; the second is fairly likely if the replacement process is quite slow, a condition which also implies that the difference in competitive abilities of the two species is small and hence likely to be easily changed by genetic variation. The third possibility would appear to be quite likely under many conditions. If the particular environmental factor is one which oscillates between the condition favoring one species at one time and the other at another time, and if the rate of oscillation is sufficiently fast as com-

WILD* M-20 with incident light attachment

One of the most important advances in microscopy for research and scientific exploration is now within easy reach of the owner of a Wild M-20.

Here, in a superbly Swiss crafted instrument, capable of the finest results in all types of microscopy, is now added a new, first order capability:

With Incident Light Attachment, the M-20 permits observation and photomicrography under bright and dark field conditions, with polarization and fluorescence. Optical quality and handling convenience are fully comparable to those found in specially designed incident light microscopes.

For full information about this most versatile microscope...and its many attachments, write for Booklet M-20.

*The FIRST name in Surveying Instruments, Photogrammetric Equipment and Microscopes.

pared to the rate of replacement of either species by the other, then the two complete competitors may, in fact, continue to coexist for a long period of time.

WERNER G. HEIM
Department of Biology, Wayne State
University, Detroit, Michigan

If one thinks of a corporation as an individual, Gordon Tullock's criticism is justified. But this "model," though sanctified by a century's evolution of U.S. legal theory, is not the only possible one. One can also think of a corporation as an aggregate of individuals

competing with other aggregates engaged in the same line of business. We assume no interbreeding of the aggregates ("mergers"). The equivalent of biological reproduction may be taken to be the hiring of new personnel. The limit of possible income is the limit of consumer demand for the goods or services of the kind offered. If there is free competition and no ecological differentiation, the most efficient aggregate will necessarily displace all others.

A tendency toward this sort of displacement is seen also in the competing of any two "species" of cells within the same individual whenever there is a

breakdown of the poorly known cybernetic controls that keep the various kinds of tissues within bounds. See, for instance, G. Crile's review of the cancer problem [*Perspectives in Biol. and Med.* 3, 358 (1960)]. Within a multicellular body that must meet certain stringent demands of the external environment, the exclusion principle cannot, of course, be worked out to its conclusion; the multicellular envelope dies first.

Werner G. Heim's remarks point up some important points which were scarcely more than hinted at in the last section of my article. We now know of many competing species, or competing alleles within a species, that manage to coexist because their relative competitive efficiencies change with the seasons, and the seasons always change. N. W. Timofeef-Ressovsky [*Biol. Zentr.* 60, 130 (1940)] has carefully described the seasonal alternation of genotypes in a beetle. Comparable studies have been made with other species by E. B. Ford in England and T. Dobzhansky and his students in this country.

In addition, our theory must take account of changes in the environment that are brought about by organisms themselves. M. J. Beijerinck's "enrichment culture" method [see F. Stockhausen, *Okologie, "Anhäufungen" nach Beijerinck* (1907)] is a direct application of the competitive exclusion principle to the problem of securing a nearly pure culture of the wanted species from a very mixed natural culture. But the method is limited by the fact that, in general, any species multiplying in a closed system will tend to make the environment less favorable for its own way of life, and thus more favorable for other forms. The result of a succession of such alterations is "ecological succession."

Facts such as these do not undermine the principle; rather, their explanation (when achieved) enriches the theory.

Names for the Sun and the Moon

The Future Scientists of America Science Club of Bergenfield, N.J., propose [*Science* 131, 380 (1960)] the proper names *Sol* and *Luna* as substitutes for the better-known *sun* and *moon* on the ground that the latter words are common nouns and not proper ones. While the argument is plausible, I think it should be pointed out that logical reasons can be adduced for *sun* and *moon*, that the question is not a scientific one but one of English usage, and that some of the assertions are too strong.

HARSHAW SCIENTIFIC

Spotlights Analytical Balances

A Balance for every weighing . . . and a Balance that will perform the weighing to the accuracy required in the shortest possible time. Most of our extensive line of domestic and imported balances is illustrated and described in the 32-page Harshaw Scientific Balance Bulletin. Do you have your copy? In addition we will gladly furnish detailed information on particular balances.

H-1642—Balance, Analytical, Ainsworth "Right-A-Weigh," Type SC. Capacity—200 grams. Sensitivity—1/10 mg. Single Pan. No weight handling. Features substitution weighing.
Price \$895.00

H-2424—Balance, Analytical, Sartorius "Selecta Rapid" model. Capacity—200 grams. Sensitivity—1/10 mg. Single Pan. No weight handling. Weights are an integral part of balance and are added by flick of external knobs.
Price \$890.00

H-2400—Balance, Analytical, Sartorius "Projecta Rapid" Model. Capacity—200 grams. Sensitivity—1/20 mg. Two pan. No weight handling up to 10 grams (weights up to 10 grams are built-in).
Price \$645.00

H-1823—Balance, Analytical, Becker Model "AB-2". Two Pan. Dial reading, chainomatic, with notched beam. Capacity—200 grams. Sensitivity—1/20 mg.
Price \$449.00

H-1905—Electrobalance, Cahn, Range Selector Model. For micro weighings quickly and accurately. Maximum range—0-100 mg. with 25 micrograms sensitivity. Four other ranges down to 0-1 mg. with increased sensitivity.
Price \$695.00

These balances are just a few of the many balances making up our complete line including Micro, Semi-Micro, Specific Gravity, etc. Write us regarding your specific need.

H-2440—Balance, Analytical, Voland Model 100N. Capacity—200 grams. Sensitivity—1/10 mg.
Price \$125.00
