

Andes has unique traits. Inca terraces, Blanco Imperial maize, and consumption of *achira* tubers may be more important in the "Sacred Valley" than anywhere else. However, the situation there predominantly parallels what I saw in the upper Huallaga and Marañón valleys in central Peru. The description this study provides of a part of Andean ethnobotany and cultural geography is good, and it should be widely used.

Adaptations of Plants

Photosynthesis and Productivity in Different Environments. Papers from a meeting, Aberystwyth, Wales, 1973. J. P. COOPER, Ed. Cambridge University Press, New York, 1975. xxiv, 716 pp., illus. \$65. International Biological Programme 3.

Diversity is the major strength of this volume, which summarizes a decade of work on photosynthesis, primarily at the whole plant, plant community, or ecosystem level. It consists of 35 chapters by 49 authors, and it assembles up-to-date information on the comparative productivity and physiology of plants in a wide range of environments. The book will have its greatest value as a reference work providing quantitative information on primary production in such diverse environments as agricultural fields, rain forests, deserts, and the seas and on the factors that affect the rate of primary production in these environments.

Troughton reviews the remarkable knowledge acquired during the past decade concerning the C_4 pathway for carbon fixation in photosynthesis and the physiology and leaf anatomy that are related to this unique adaptation. His review is important because of the relationship of the C_4 system to plant productivity and adaptation. Loomis and Gerakis discuss the role of the C_3 and C_4 pathways in plant productivity. They report that when growing at low latitudes C_4 species are the world's most productive plants. At high latitudes, however, C_3 species have greater productivity. Loomis and Gerakis's analysis of the relationship of leaf area index, leaf angle, and light to maximum crop productivity is done well. They point out that a high leaf angle is of value only when the soil is covered with a dense canopy of leaves. Their analysis clears up some of the confusion over the relationship of plant productivity to the leaf area index, and they give examples of an optimum-type re-

sponse, a plateau-type response, and the response typical of some of the highly productive C_4 species, in which productivity continues to increase with increasing leaf area to indices as high as 20.

During the last decade, it has been shown that water controls the rate of photosynthesis not only through stomatal closure but also by directly affecting the biochemical processes. Slavik discusses this work and points out that the relative importance of stomatal processes and direct biochemical effects of water in controlling CO_2 uptake depends on the environmental conditions, the water stress within the plant, and the species of plant.

A much greater understanding of the effect of temperature on photosynthesis has also been obtained in recent years. It is now known that the upper limits of temperatures at which photosynthesis is possible vary from 35°C to more than 60°C, depending on the species. Likewise, species differ markedly in their ability to perform photosynthesis at low temperatures. Some species are sensitive to mere chilling, whereas in others photosynthesis proceeds until the leaf tissue actually freezes. Although the reasons for these differences in sensitivity to temperature are not yet understood, it is clear that during evolution remarkable differences in ability to tolerate extremes of temperature have developed. This suggests that man may be able to alter the temperature sensitivity of a given species markedly once an understanding of the mechanisms of tolerance is attained.

The role of radiant energy in terrestrial and aquatic communities is discussed at some length in the book. The greatest value of the chapters on that subject is to bring the reader up to date on the gradual progress that has been made during the past decade and to increase his understanding of the role of light in communities of plants with different leaf structures.

A large section of the book is devoted to primary productivity in various environments. These chapters, on the whole, are done well, and they pull together information that will be useful to the ecologist or agricultural researcher. Finally, the possibility of enhancing photosynthetic productivity is evaluated in the light of major research efforts during the past decade on the alteration of photosynthesis through genetic manipulations. Although the practical results of those efforts are not impressive, the groundwork has been laid for a significant accomplishment in the years ahead.

In his introduction, the editor writes: "The present volume sets out to provide

a comparative survey of the photosynthetic activity of different ecosystems, both terrestrial and aquatic, including an examination of the physiological basis of such activity and its possible modification by management and breeding." Many of the reviews tend to be weighted with citations of the author's own work to the exclusion of other work that might (or should) have been cited, but because the authors represent many of the world's prominent laboratories where the physiology and ecology of plant productivity are being investigated, the volume comes nearer to reaching the editor's stated goal than anything yet published on photosynthesis.

Photochemistry

Excited States in Organic Chemistry. J. A. BARLTROP and J. D. COYLE. Wiley, New York, 1975. xii, 376 pp., illus. \$39.50.

A number of books in organic photochemistry appeared about a half decade after the field began to undergo exponential growth about 1960. These are generally quite good but are now ten years old. Thus the timing of Barltrop and Coyle's book is right.

The book covers the literature and the theory of photochemistry. The first two chapters cover the basic principles of light absorption, multiplicity, excited states and properties, types of transition, and modes of formation of excited species. A third chapter deals with photophysical processes such as fluorescence, radiationless decay, and Franck-Condon effects—thus emphasizing time-dependent behavior—and a fourth considers quenching processes such as energy transfer, heavy atom quenching, and electron transfer. Chapter 5 discusses different methods of deriving photochemical reaction mechanisms. Chapter 6 deals with the concepts of reaction allowedness and forbiddenness. A seventh chapter considers mechanisms of carbonyl chromophore reactions, chapter 8 turns to carbon-to-carbon π -bond chromophore transformations, and chapter 9 treats aromatic photochemistry. Chapters 10 and 11 concern themselves with nitrogen-containing molecules and saturated species, respectively. A useful brief appendix on group theory is included.

The book is quite well done. Writing such a book is a challenge, because pho-

tochemistry has a vast literature, and because a theory that is in vogue or a reaction that is of interest at a given moment may not be so a few years later. Barltrop and Coyle have handled the problem well. They have emphasized current literature over older literature perhaps a little more than the reviewer might have wished, but the treatment is current while still giving historical perspective for the most part.

The number of errors is small, but it seems to be the duty of a reviewer to find errors or weak points, and this reviewer will do so. Among the things one might mention is the use of "stereospecific" on p. 204 where "stereoselective" is meant. On p. 167 there is a mix-up of references so that Longuet-Higgins is credited in the wrong place for the wrong contribution. The discussion of meta electron transmission on pp. 287-290 quotes the reviewer's theoretical contributions with reference to work that was in fact done later. The same occurs in connection with discussion of $n-\pi^*$ photochemistry. The reviewer would be less than human if he did not comment on his name's being misspelled throughout chapter 6. Finally, although Möbius benzene is discussed, there is no general discussion of the difference between Möbius and Hückel systems. An author index would have been helpful, since so many photochemists look things up by reference to their memory of who did the work. As can be seen, though, these deficiencies will not necessarily detract from the general usefulness of the text.

Having aired some minor complaints, the reviewer can turn to some strong points. First, there is a very broad coverage of different types of photochemical reactions, and the examples are quite representative. Second, the interpretations given are lucid and concise and approximate closely those of the authors of the original literature. Third, there is good balance between theory and fact. Finally, there is sufficient material to provide good background for someone new to photochemistry and also to intrigue the specialist.

In conclusion, this book will be of use to active researchers in photochemistry and to those graduate students who can specify an expensive gift at Christmas-time.

The only really negative comment about the book concerns the price. An author often does well to make a low price a condition for giving his manuscript to a given publisher.
