Icelandic Health Records

Recent News of the Week articles by Martin Enserink (14 Aug., p. 890 and 30 Oct., p. 859) and an editorial by Henry T. Greely (*Science's* Compass, 23 Oct., p. 625) clearly describe the discord over plans by the government of Iceland to create a central health record database and give a private company, deCODE Genetics, exclusive rights to analyze and market the data.

It needs to be emphasized that the proposed bill allows deCODE to bypass review by human subjects committees and seeks to strip patients of rights that are considered fundamental in Westernized societies.

First, while the bill provides an "opt-out" clause, no informed consent will be obtained from individuals whose data will be included in this database that targets insurance companies and HMOs as prospective buyers.

Second, and even more troublesome, is a provision in the bill that would give deCODE exclusive rights to market the data for 12 years, preventing patients from participating in studies and databases that might be created in the future by competing entities. Thus, this provision limits a patient's ability to use health records, including genetic information, even when the patient's intent may be to seek understanding and solution of their affliction. Furthermore, such legalized monopoly of genetic research threatens academic freedom in Iceland.

The Icelandic government, which is skilled at managing fisheries, seems to be inclined to treat our health records and genetic information like a seafood product. Although similar plans would not be taken seriously in other Western cultures, the proposed bill could motivate others to encroach on academic freedom and to trample on a patient's rights for monetary gain in different parts of the world. Therefore, it is of paramount importance that leaders in the international scientific community, especially those concerned about ethical aspects of genetic research, join patient advocates, physicians, and scientists in Iceland in condemning these plans.

Protein Data Bank Deposits

Since the Protein Data Bank (PDB) inaugurated the "Layered Release Protocol" on 9 July 1998 (F. E. Bloom, "Policy Change," *Science's* Compass, 10 July, p. 175) (www.pdb.bnl.gov/ and www2.ebi.ac.uk/pdb), results have exceeded our highest expectations. Specifically, since July we have received 931 new entries, of which 813 were submitted by means of our latest data deposition software (AutoDep 2.1), which allows for "release on publication." For less than 22% of these, "on-hold" is requested, and the rest have been either immediately released or held

until publication (see table above for details). This is in sharp contrast to the situation just a year ago, when more than 75% of new entries were requested to be put "on-hold" for 1 year.

AUTODEP 2.1 ENTRIES (FROM 9 JULY 1998 TO 28 NOVEMBER 1998)		
Category	No.	%
Request immediate release	245	30.1
Waiting for publication	393	48.3
Request on-hold	175	21.5

This is an enormous tribute to the journals that have set the new policy requiring "Release on Publication," as well as to the PDB, which instituted the "Layered Release Protocol," making it possible to access data concurrently with publication.

It is clear that there has been a profound change in the attitude of the vast majority of experimental crystallographers and nuclear magnetic resonance spectroscopists toward releasing their data either immediately or at the time of publication. This is an exciting development for structural biology that will have a positive impact on other scientific disciplines, industrial research, and education.

The Handy-Dandy Kitchen Device

In gray tree frogs, the duration of males' mating calls is correlated with enhanced genetic fitness among offspring (A. M. Welch *et al.*, *Reports*, 19 June, p. 1928). Perhaps the same genes that enable some frogs to sustain longer calls also confer a survival advantage to their young (E. Pennisi, *Research News*, 19 June, p. 1837). If so, this may be an example of a more general, but underappreciated, evolutionary process, in which fitness is increased through the combined effect of multiple inherited characteristics. In the case of gray tree frogs, a characteristic with little if any apparent adaptive significance (longer calls) may be associated with oth-

MILLIPORE

In-gel digestion of "spot 223" of 2D gel before and after ZipTip_{C18}

pure spectra

Now desalt femtomoles of peptide in less than 60 seconds with Millipore's new ZipTip_{C18} pipette tips for sample preparation. Elute your sample in 2-4 μ L of acetonitrile/water. Ideal for sample preparation prior to Mass Spectroscopy.
