

Worldwide Scientific Publishing Activity

IF WE VIEW SCIENTIFIC ACTIVITY AS AN indicator of wealth, and if we believe that publishing activity in peer-reviewed journals is correlated to scientific activity, then we can take the amount of papers published by individuals of a nation (divided by its total population) as an indicator of that nation's wealth. In the case of scientific activity, there is the expectation that it not only

reflects today's wealth, but also promises future wealth through the practical application of the scientific knowledge generated.

We analyzed this indicator using the MEDLINE database of biomedical journal articles (1), which contains entries including the main address of the authors and the date of the publication. A first static analysis (measuring the papers published per inhabitant during 1996–2001) offered no surprises (see panel A of figure). The differences between First, Second, and Third Worlds are easily seen in a 10-fold difference in the amount of articles published per inhabitant.

Being aware that developed countries dominate the process of publication and that this might bias the analysis (2), and in order to show the evolution of scientific activity in different areas of the world, we analyzed the relative evolution of publication activity in two periods, a parameter that should be independent of the dominance of developed countries in publishing. This comparison yields a disturbing result (see panel B of the figure): Most countries with low levels of publication (brown in panel A) also suffer from a negative publication trend (brown in panel B). This means that, unfortunately, the gap between scientifically active countries and the rest is apparently widening rather than closing.

Scientific funding agencies worldwide should take this into account. As claimed repeatedly (3), projects that train scientists from developing countries and help create research

groups in those countries must be promoted, because we feel that scientific development will bring these countries socioeconomic development and because the global scientific community cannot afford to waste the intellectual capacity of developing countries.

Collecting Biological Materials

I READ RICHARD STONE'S PROFILE OF biologist Gary Strobel ("Biologist gets under the skin of plants—and peers," *News Focus*, 31 May, p. 1597) with great interest. I would like to know if Strobel abides by local regulations about collection and exportation of biological materials in the many countries where he has worked. I deeply hope that Strobel does not see Third World countries merely as raw materials providers for technological developments, for which our people must later pay high royalties. The use of Third World (and all) natural resources should result in mutual and equitable benefits. And, as Strobel may understand, this is much more than simply returning a portion of the profits to the local communities. Third World countries are under tremendous pressure to comply with patents and royalties from developed countries (and many times these patents are derived from Third World resources); scientists all around the world should be encouraged to comply with each country's regulations about the collection and exportation of biological materials.

VIRGINIA ABDALA

Instituto de Herpetología, Fundación Miguel Lillo, Miguel Lillo 251, 4000 Tucumán, Argentina.

We analyzed over 4.2 million entries from MEDLINE corresponding to articles published during 1989–2001. We identified the countries in the authors' affiliations for 4.0 million entries. Countries that became independent after the dissolution of former countries during the period analyzed were counted as one country (namely, the Union of Soviet Socialist Republics, and the former federal republics of Yugoslavia and Czechoslovakia). The population of each country as of May 2002 was taken from (4). (A) Approximate amount of publications for the years 1996–2001 per million inhabitants by country: dark green, 10,000; light green, 1000; yellow, 100; light brown, 10; dark brown, 1. (B) Ratio of the number of publications for 1996–2001 to the number of publications for 1989–95: green tones, positive trend; yellow, stable trend; brown tones, negative trend. Gray indicates that no publication corresponding to that country was found.

Response

I HAVE ALWAYS OBTAINED PERMISSION to collect materials wherever I have gone. In addition, I acquire all necessary permits from the U.S. Department of Agriculture to bring disease-free samples into the United States. The arrangement generally is that if an organism proves valuable, then the supporting organization and I will discuss the disposition of financial benefits that the local community may derive. This plan is laid out at the outset. One of the main goals of the program is to help scientists in developing countries improve their scientific infrastructure. This is accomplished in a multitude of ways, including giving investigators opportunities to work in my lab for advanced training. In addition, local investigators are invited to become involved directly in the research. This has been true with scientists from Nepal, China, Morocco, Venezuela, Israel, Papua New Guinea, India, and Korea, to name a few countries with which I have been involved. Many people do not understand that to find a successful drug is difficult and expensive, and therefore a lot of time cannot be spent discussing matters of income where income may not ever exist. Discovery is the least expensive of all of the steps required in drug discovery. Ul-

time drug development may cost up to \$300 million. Compounds fail for many technical reasons, including toxicity, availability, side effects, and inability to reach the appropriate site. Nevertheless, it is absolutely critical to me that local people get energized about the novel and important biological prospects that exist in the forests around them and be encouraged to study them and learn about their promise and potential. It is also essential that more efforts be made to save these important biological resources before they disappear forever.

C-Reactive Protein and Atherosclerosis

THERE IS A CREDIBLE ALTERNATIVE HYPOTHESIS that may explain the challenging observation that many states not heretofore regarded as inflammatory are associated with minimal C-reactive protein (CRP) elevation, discussed in Gary Taubes' article "Does inflammation cut to the heart of the matter?" (News Focus, 12 April, p. 242). Many other noninflammatory

factors (demographic, genetic, life-style, and medical) can be added to those cited in the article, including depression, chronic fatigue, poor physical conditioning, high-protein diet, hypertension, insulin resistance, and albuminuria. Many of these conditions indicate suboptimal physical status and may reflect tissue injury. CRP has long been used clinically to evaluate the presence and degree of inflammation (1), classically defined as the response to tissue injury. I propose that tissue injury itself causes CRP elevation, even when no inflammatory response is apparent. Minor CRP elevation would thus identify individuals who bear an increased burden of tissue damage, resulting from a variety of causes (2). It is highly likely that among these is cumulative oxidative stress, which is strongly implicated in the pathogenesis of aging (3). Such biologically older individuals have a greater likelihood of manifesting diseases associated with aging or of dying (4).

Inappropriate use of screening tests can be harmful (5), and many have concluded that routine use of CRP testing is premature (6–12). CRP testing does not meet three major criteria for an effective screening test (13): (i) Accuracy is uncertain; we have no idea of how many individuals are incorrectly identified as high risk (14). (ii) Reliability

We're In It For The Science

The **National Cell Culture Center** is a non-profit resource sponsored by the NIH to support basic research by providing access to cell culture services at minimal cost. Working with the Center, your cell line or custom protocol is adapted for larger scale production. Cells or cell secreted proteins are delivered in the quantity and frequency you desire, enabling you to focus more of your valuable resources on fundamental research problems.

Thousands of scientists from every major research institution throughout the country have accessed the Center for their cell culture needs. Let us help you with your research. *Visit us on the web at www.nccc.com*

Sponsored by the National Center for Research Resources, National Institutes of Health.
