

day long, but he prolongs his day far into the night. By day his song is not very musical, but at night it seems softened and subdued almost to sweetness. The country boys call him the "sheep-sheep shear-shear-shear" bird, as an imitation of his song. The first two notes are uttered sharply with a considerable pause between them then, the last very rapidly — nearly run together.

Two other birds are not uncommon night singers — the grasshopper and henslow's sparrows (*Ammodramus s. passerinus* and *A. henslowi*), especially the latter. His modest little song is so drowned out during the day by the larger birds that he must sing at night if he be heard at all. I have often heard his note well into the night.

There is one winter night singer, the chestnut-colored long-spin (*Calcarius ornatus*). As one wanders over the snow-clad hills on some frosty night, he may near the clear *chee-ho* of this bird starting from the snow where he lies hidden.

The Earth as a Conductor.

In reference to the communication on the use of the ground in an electric circuit, June 16, you may allow me to say: The earth is not a conductor of electricity in any sense, only as a convention. All Du Moncel's measurements, and they were many, gave the resistance of the earth as about 100 ohms. This resistance is negligible in long circuits, telegraphic or telephonic, but not in short circuits.

On the principle of contact electricity (see Ayrton and Perry, Jenkins or Gorden) it was wrong to place a copper plate at one end and a tin plate at the other, as their contact or connection by wire would produce a current along the wire. Nor was it proper to put charcoal or carbon or iron around either plate on the same principle. Both plates, preferably, should be of copper surrounded by sulphate of copper. There is considerable resistance offered in the passage of a current from one kind of material to another (see Jenkin passim).

The earth may, for convenience, be called a reservoir of electricity, but its quantity is always constant and no electricity can be taken from it at one point without putting an equal quantity into it at another point. The action or roll of the earth in the circuit is like this. Consider a lake of large dimensions with a

lift and force pump at A connected with a pipe which crosses the lake to B; the water lifted at A and forced over to B falls into the lake, but not a drop of it ever gets back to A.

If you will consider a ground wire in a large telegraph or telephone office with a number of circuits of variable resistances and different polarities attached to it you will see that it is absurd to say that a positive current from one battery goes down that ground wire and off to a distant point while at the same instant a positive current from a distant battery comes up the same wire. That is the common sense view of it, and it is supported by Kirchhoff's law, $\sum C = 0$, or the sum of all the E M F's or currents meeting in a point equals nothing. In fact, the ground wire in a large office may be cut (as I have often seen it done for experimental proof) without stopping communication. When three or more wires are joined to the same ground either one of the wires acts as a return wire for the others when the ground wire is cut. But when all are open at once, then the ground comes into play to form the circuit for the first one that closes. It is also useful as a regulator of current, but the manner of doing this is not properly introduceable here.

If nothing had been said of the use of tin at one end and copper at the other the resistance of 102 ohms as found would indicate a good ground. But as some current probably arose from

their use, doubt is cast upon the measurements. Still, on the whole, the ground was as good as is usually made.

One hundred ohms' resistance in the earth circuit under all circumstances should be reckoned on and may be regarded as a constant.

On the Evolution of the Habit of Incubation.

It may be stated as a general rule that harmless snakes produce their young by means of eggs, while poisonous serpents are viviparous, to which fact they probably owe their generic appellation of "vipers." The oviparous snakes, like most other reptiles, deposit their eggs in a sunny spot, and never trouble themselves about the incubation, but leave the eggs to hatch out as best they may under the influence of the sun's heat. There is, however, a very curious though authentic instance on record of a caged python, in the *Jardin des Plantes*, at Paris, which hatched out her own eggs. She laid fifteen in all, and then coiled herself around them, and so incubated them in much the same manner as a setting hen, her temperature being observed to increase perceptibly during the period.

This strange fact, whether an anomaly or whether a natural habit of the pythons, seems to throw considerable light on the evolution of the habit of incubation, so universal among birds, for it must be remembered that the bird is closely allied to the reptile, and is in fact but a higher form of the type. This relationship is clearly shown by the study of the morphology of the bird's organs, for every part of a bird's body is but a modification of the corresponding part of the reptile; it is also shown by the fact that birds are found in geological strata immediately after the reptiles, and hence must have appeared upon the face of the earth at a later period. Were any further proof necessary, it is furnished in an irrefutable manner by the science of embryology, for the bird passes in the egg through all the reptilian stages of development before it is finally hatched out in its perfect form.

This being the case, we may rest assured that the habit of incubation has been evolved at some time during the evolution of reptiles into birds, and hence this case of the python hatching its own eggs acquires exceptional interest.

We may premise that the habit could never have been evolved unless it were of some value to the species, but we must at the same time admit that the incubated egg would in all cases hatch out far in advance of that heated only by the sun, hence those individuals which thus appeared earlier than their brothers ran a better chance of surviving in the struggle for existence. So far, so good, but how did the habit originate? What first led snakes or other reptiles to think of hatching out their eggs? That it was not intelligence we can safely assert, for all who have had any experience in keeping snakes, agree in stating that their intelligence is of the lowest order. I am therefore inclined to believe that what first led animals to incubate their eggs was the heat developed in the egg during the process of hatching. Snakes are exceedingly fond of heat, in fact I have known them to injure each other in cages in the attempt to retain the warmest places. Hence we can infer that if, when basking in the sun, a snake chances to lie near its eggs, especially if these have already begun to hatch, it will soon feel their heat and so be led to coil more closely about them, and while thus warming itself it will at the same time hasten the process of incubation.

The next question that arises is, how this habit of incubating her eggs, even when thus acquired, will be transmitted to the offspring, for if not transmitted, the habit could never become general.

So little is known of the principles of inheritance that we cannot hope to solve this problem at present. Even Darwin, who made a life-long study of the subject, and to whom we are indebted for the ingenious theory of *pangeneses*, was forced to admit our abject ignorance of the laws of transmission of characters from parents to children. We can, however, infer that those serpents most susceptible to the cold would be most likely to remain by their eggs, and this susceptibility to cold would tend to be inherited by the young.

Moreover, when we remember what unexplainable cases of inheritance occur, such as special movements during sleep, we must admit that even the tendency in a snake to incubate its eggs may also be transmitted, the more so as we have an indisputable inheritance of the same nature daily shown us in the case of birds, for the tendency of the parents to incubate their young is in all cases inherited by the offspring.

Another Ancient Argillite Quarry Near Trenton,

ON the left bank of Neshaming "Creek," Bucks County, Pennsylvania, about three-fourths of a mile above the mouth of Labaska or Mill Creek, I discovered at the base of the cliffs of metamorphosed slate that there overhang the stream, on June 23, another ancient work-shop where blocks of argillite, lying *in situ*, have been chipped into "turtle-backs."

A layer of chips, hammer-stones, and the now familiar rude leaf-shaped forms is laid bare for several hundred yards where the stream has worn away the margin. The blocks of workable stone in various instances show peckings upon their sides, as do similar specimens at Point Pleasant, inferably made by the ancient workmen to split them with the grain.

No search has yet been made for diggings and refuse-heaps higher up the slope, nor has excavation been made into the exposed layers; but thus far the story of the workings on Gaddis' Run, near Point Pleasant (Bucks County, Pennsylvania), discovered on May 22, seems to be repeated, though on a smaller scale. There we were twenty-five miles from Trenton; here we are but fifteen.

H. C. MERCER.

Do Nestlings Drink.

This question suggested itself to my mind very lately, when I observed the following, and to me, entirely new fact:

A piazza-roof, on which my windows open, is provided with a

shallow gutter, in which there is a considerable accumulation of the winged seeds from a neighboring tree. These were standing in shallow water, left there by the recent rains.

I observed a robin alight on the roof, and noticed that she picked from the gutter a bunch of those seeds, which she held in her bill while she seemed to be preparing to fly away.

Presently, apparently dissatisfied with what she had picked up, she dropped the seeds, and moving to a place where they were lying in a thicker bed, she gathered a much larger mass of them, about as many as her bill would hold together. After gathering them and satisfying herself that she had enough, she deliberately dipped the mass into the water and flew away with it to a distant tree. Perhaps some of your readers may suggest a truer explanation; but to me she seemed to be carrying a supply of water to her brood in what was no inadequate substitute for a sponge.

BOOK-REVIEWS.

Logarithmic Tables. By PROFESSOR G. W. JONES. Ames, Iowa, the Author.

THE title of this book does not exactly describe its contents. The strictly logarithmic tables are only about one-half of those given. The arrangement of the tables, of which there are eighteen, has been made to meet the wants of those who desire to have, in a handy form, tables to be used in computations covering a wide range. Table I. is a four-place, of numbers from 1 to 1,000, followed by one of the same accuracy giving the six principal trigonometric functions, and of the lengths of arcs in radians. The first five degrees of the quadrant are given to each five minutes, the following to each ten minutes, with differences for single minutes. A table giving the squares, cubes, square-roots, cube-roots, and reciprocals of the numbers 1, 2, 3, 99 is also given. Table III. is a six-place table of numbers, the side numbering being carried to only three figures instead of four, as is usual in

CALENDAR OF SOCIETIES.

THE MODERN MALADY; or, Sufferers from 'Nerves.'

An introduction to public consideration, from a non-medical point of view, of a condition of ill-health which is increasingly prevalent in all ranks of society. In the first part of this work the author dwells on the errors in our mode of treating Neurasthenia, consequent on the wide ignorance of the subject which still prevails; in the second part, attention is drawn to the principal causes of the malady. The allegory forming the Introduction to Part I. gives a brief history of nervous exhaustion and the modes of treatment which have at various times been thought suitable to this most painful and trying disease.
