

Eight independent experiments of this sort were made, the orientation of the respective blocks being successively interchanged as was also the order of irradiation of the respective pairs so that positional or such chronological difference might not influence the means of all these results. These mean values of φ together with the corresponding periods of irradiation, t , are given in the table and represented

TABLE I

t (in minutes)	φ (in days)	A.D.	t (in minutes)	φ (in days)	A.D.
0	5.55	.06	140	8.20	.07
35	8.09	.11	175	8.18	.07
70	9.24	.09	210	8.10	.08
105	8.36	.10	245	8.09	.08

graphically in the figure. In the table also is given the A.D. of each mean (the mean deviation divided by $\sqrt{8}$) which is employed as a precision measure.

The indication of a maximum point on the graph in the interval, 35 to 105 minutes, is statistically significant, and the decline followed by attainment of an almost level plateau is a surprising result. Here, too, the precision measures indicate that this is not due to mere chance.

THE EFFECT OF SUNLIGHT ON HUMAN BLOOD CELLS

EXPERIMENTS were made to elucidate the action of sunlight on human cells under the condition of general insolation. The first experiments concerned the cells which are easiest to obtain, namely, the red blood corpuscles. The results of these experiments are described below.

It was found first that, in accord with the results obtained by Pfeiffer and Bayer, Hausman and Loewy, and Löchner, red corpuscles suspended in a salt solution exposed to direct sunlight gradually disintegrate and hemolyze. This disintegration occurs, however, only if the corpuscles are illuminated by intensive sunlight (clear sky, dry air, at noon). Under such condition the first hemolysis is noticed 10 minutes after beginning of insolation. Diffuse sunlight does not produce any hemolysis. Further experiments show, however, that even diffuse light which is fifty times as weak as direct sunlight makes the corpuscles less resistant and accelerates their spontaneous hemolysis when after the illumination they are kept in the dark in a physiological salt solution. After the exposure of the suspension of corpuscles to direct sunlight their resistance against poisons and hypotony is

markedly diminished. But among the rays of sunlight only visible rays decrease this resistance. If the corpuscles are exposed to direct sunlight in quartz tubes no decrease or even an increase of the resistance is observed. Special experiments showed that ultra-violet rays, if they are weak or act for a short time, increase the resistance of the corpuscles and protect them against the harmful effect of visible rays. However, strong ultra-violet rays from a mercury vapor lamp destroy the red corpuscles.

In *in vivo* experiments it was found that a total insolation of men lasting 10 minutes (December, January, in Arizona) increases the resistance of young red corpuscles and decreases the resistance of old corpuscles, the latter being more sensitive to visible light. The insolation of the same men for one hour increases the resistances of all their corpuscles very markedly, but only if the sunlight contains a sufficient amount of ultra-violet rays (clear sky). This increase of the resistance is not lasting and disappears within twenty-four hours. When the sky is partially covered by clouds and the humidity is high or when sunlight is filtered through glass plates (6 mm thick) a marked decrease of the resistance of all corpuscles is observed, and this decrease does not always disappear within twenty-four hours.

The author's experiments twenty years ago showed that the permeability of protoplasm of plant cells for water soluble substances is greater in light than in the dark. This observation was confirmed later by many scientists not only on plant but also on animal cells. We might expect, therefore, the same action of light on red corpuscles. Indeed the present experiments show that the permeability of red corpuscles for water soluble substances is increased by sunlight, and this effect is due to the visible light in this case, too. Human red corpuscles were investigated in respect of their permeability for grape sugar. It may, therefore, be assumed that the nutrition of red cells is enhanced by the action of sunlight. As the chemical and physical structure of red corpuscles is similar to that of colorless cells, the results obtained on red corpuscles can be extended to all cells of our organism, and it is likely that sunlight increases the nutrition of our organism in general.
